

Это цифровая копия книги, хранящейся для иотомков на библиотечных полках, ирежде чем ее отсканировали сотрудники комиании Google в рамках ироекта, цель которого - сделать книги со всего мира доступными через Интернет.

Прошло достаточно много времени для того, чтобы срок действия авторских ирав на эту книгу истек, и она иерешла в свободный достуи. Книга иереходит в свободный достуи, если на нее не были иоданы авторские ирава или срок действия авторских ирав истек. Переход книги в свободный достуи в разных странах осуществляется ио-разному. Книги, иерешедшие в свободный достуи, это наш ключ к ирошлому, к богатствам истории и культуры, а также к знаниям, которые часто трудно найти.

В этом файле сохранятся все иометки, иримечания и другие засиси, существующие в оригинальном издании, как наиминание о том долгом иути, который книга ирошла от издателя до библиотеки и в конечном итоге до Вас.

Правила использования

Комиания Google гордится тем, что сотрудничает с библиотеками, чтобы иеревести книги, иерешедшие в свободный достуи, в цифровой формат и сделать их широкодоступными. Книги, иерешедшие в свободный достуи, иринадлежат обществу, а мы лишь хранители этого достояния. Тем не менее, эти книги достаточно дорого стоят, иоэтому, чтобы и в дальнейшем иредоставлять этот ресурс, мы иредиринали некоторые действия, иредотвращающие коммерческое исиользование книг, в том числе установив технические ограничения на автоматические заирсы.

Мы также иросим Вас о следующем.

- Не исиользуйте файлы в коммерческих целях.

Мы разработали иrogramму Поиск книг Google для всех иользователей, иоэтому исиользуйте эти файлы только в личных, некоммерческих целях.

- Не отиравляйте автоматические заирсы.

Не отиравляйте в систему Google автоматические заирсы любого вида. Если Вы занимаетесь изучением систем машинного иеревода, оптического распознавания символов или других областей, где достуи к большому количеству текста может оказаться иолезным, свяжитесь с нами. Для этих целей мы рекомендуем исиользовать материалы, иерешедшие в свободный достуи.

- Не удаляйте атрибуты Google.

В каждом файле есть "водяной знак" Google. Он иозволяет иользователям узнать об этом ироекте и иомогает им найти доилнительные материалы ири иомощи иrogramмы Поиск книг Google. Не удаляйте его.

- Делайте это законно.

Независимо от того, что Вы исиользуйте, не забудьте ироверить законность своих действий, за которые Вы несете иолную ответственность. Не думайте, что если книга иерешла в свободный достуи в США, то ее на этом основании могут исиользовать читатели из других стран. Условия для иерехода книги в свободный достуи в разных странах различны, иоэтому нет единых иравил, иозволяющих определить, можно ли в определенном случае исиользовать определенную книгу. Не думайте, что если книга иоявилась в Поиске книг Google, то ее можно исиользовать как угодно и где угодно. Наказание за нарушение авторских ирав может быть очень серьезным.

О программе Поиск книг Google

Миссия Google состоит в том, чтобы организовать мировую информацию и сделать ее всесторонне доступной и иолезной. Программа Поиск книг Google иомогает иользователям найти книги со всего мира, а авторам и издателям - новых читателей. Полнотекстовый иоиск и этой книге можно выполнить на странице <http://books.google.com/>

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

MONOGRAPHIA
APPUM ANGLIAE.
PARS TERTIA.

SPECIERUM / NOMINUM SPECIFICORUM SY-
NOPSIS EXHIBENS.

Multa fecisti tu JEHOVA Deus meus, mirabilia tua: et cogitationes tuas erga nos, nemo est qui ordinare possit tibi: si enuntiare et eloqui velim, plura sunt quam ut narrentur.

Ps. xl. 9.

Reddere personæ scit convenientia cuique. IIor.

VOL. II.

A

SYNOPSIS SPECIERUM.

MELITTA. (a)

*O*s proboscide subcylindrica, porrecta, linguam brevem, planiusculam, exerente.

Antennæ mediæ, aculeatis subclavatæ articulis 13; maribus filiformes articulis 14.

Oculi laterales, subovales, integri.

Aleæ planæ.

Aculeus punctorius, reconditus.

*. a.

Os linguâ apice bilobâ; valvulis plicatis.

Labium anticè obtusangulum.

Corpus villosum.

succincta. 1. *M. nigra*, albido-villosa; thorace fulvo; abdomine ovato; segmentis margine albis. (1)

fodiens. 2. *M. nigra*, albido-villosa; thorace fulvescenti; abdomine conico, basi subretuso; segmentis margine pallidis. (2)

*. b.

Os linguâ subtruncatâ, auriculatâ.

Labium anticè obtusangulum.

(a) Tab. 1—4.

Abdomen

Abdomen conicum, supra gibbum.

Corpus glabrum.

Obs. *Antennæ femineæ apice recurvæ.*

3. M. atra; fronte maculatâ; tibiis posticis albido *annulata*.
annulatis. (1)
4. M. atra; fronte maculatâ; tibiis omnibus flavo *annularis*.
annulatis. (2)
5. M. atra; tibiis flavis, nigro *annulatis*; antennis *dilatata*.
scapo patelliformi. (3)
6. M. atra; fronte maculatâ; abdomen segmento *signata*.
primo margine utrinque albo. (4)

***. a.

Os linguâ acutâ, auriculatâ.

Labium inflexum, anticè emarginatum.

Abdomen ovatum, glabrum, supra gibbum.

Corpus subpilosum.

Obs. *Antennæ femineæ apice recurvæ. Ab-*
domen masculum lineare; antennæ submonili-
formes.

7. M. atra; abdomen ferrugineo, apice nigro. (1) *gibba.*
8. M. atra; abdomen rufo, apice, pedibusque, *Geffrel-*
nigro-piceis; maxillis, tarsis, tibiisque aitacis,
rufescensibus. (2)
9. M. aterrima; abdomen ferrugineo, basi apice- *Sphecoi-*
que nigro; alis nigricantibus. (2)
10. M. atra; antennis piceis, thorace longioribus; *monilior-*
abdomine cingulo rufo. (3)
11. M. atra, glabriuscula; abdomen piceo, nitido; *picea.*

SYNOPSIS SPECIERUM. (*Melitta.*)

segmentis intermediis basi et utrinque ferrugineis. (5)

- divisa.* 12. *M. atra*; abdomine subovali, nitidissimo, cingulo ferrugineo; antennis thorace brevioribus. (6).

* *. b.

Os linguâ acutâ, auriculatâ; valvularum loris elongatis.

Labium pectinatum, appendiculatum.

Abdomen subovale, ano rimâ perpendiculari.

Corpus subvillosum.

Obs. *Antennæ* femineæ apice recurvæ. *Labium* masculum pectinatum, absque appendice; *corpus* elongatum; *anus* rimâ nullâ.

- quadri-*
cincta. 13. *M. atra*, cinereo-subpubescens; abdomine convexo, segmentis margine albis; pedibusanoque, villoso-pallidis. (1)

- rubicun-*
da. 14. *M. atra*, rufescente-pubescent; abdomine segmentis margine albis; tarsis, tibiisque posticis, fulvis. (2)

- flavipes.* 15. *M. nigro-ænea*, nitida; pedibus flavis. (3)

- seladonia.* 16. *M. nigro-ænea*, pallido-subpubescens; abdomine segmentis margine pallidis. (4)

- cærata.* 17. *M. virdi-ænea*, nitida; abdomine nigro-æneo. (5)

- leucopus.* 18. *M. ænea*; abdomine nigro; antennis subtus fulvis; tarsis albidis. (6)

- Morio.* 19. *M. ænea*; metathorace cœrulecenti; abdomine nigro. (7)

20. *M.*

SYNOPSIS SPECIERUM. (*Melitta*.)

7

20. *M. nigra*, nitens; antennis subtus fulvescentia minuta. tibis. (8)
21. *M. atra*, albido-villosula; abdomine subovato; *vilosula*. antennis subtus, tarsisque, rufescens. (9)
22. *M. atra*, glabriuscula; abdomine nitidissima minutissima. (10)
23. *M. nigra*, glabriuscula; antennis subtus flavis; *nitidiuscula*. maxillis, labio, tarsisque, albidis. (11)
24. *M. atra*, pallido-villosula; abdomine nigro, *lævis*. lævi, nitidissimo. (12)
25. *M. atra*, pallido-villosula; abdomine subpubescentia punctulata, punctulato, segmento primo lævi, nitidissimo. (13)
26. *M. nigra*, griseo-subpubescens; abdomine submalachitico. tomentoso. (14)
27. *M. nigra*; antennis thorace longioribus, fulvescentibus; abdomine nitido, segmentis intermediis basi albjs. (15)
28. *M. nigra*, rufescente-pubescentia; abdomine subfulvotomentoso, segmentis margine fulvis, intermediis basi utrinque pallidis. (16)
29. *M. atra*, albido-subvillosa; abdomine segmentis allipes. inter mediis rufis, fasciâ, punctisque lateralibus, nigris; labio flavo. (17)
30. *M. atra*, cinereo-subvillosa; abdomine segmentis anticis rufis, maculâ mediâ, punctisque lateralibus, nigris. (18)
31. *M. atra*, glabriuscula; abdomine nitidissimo, obovata. obovato, segmentis basi albis. (19)
32. *M. atra*, rufo-subpubescens; thorace ferrugineo; *lævigata*.

SYNOPSIS SPECIERUM. (*Melitta.*)

ruginoso; abdome nitidissimo, segmentis intermediis basi pallescentibus. (20)

leucozonia. 33. M. atra, cinereo-pubescent; abdome segmentis intermediis basi albis. (21)

xanthopus. 34. M. nigra, rufo-pubescent; thorace ferrugineo; abdome segmentis utrinque basi pallidis; pedibus posticis testaceis. (22)

quadrinotata. 35. M. atra, cinereo-subpubescent; abdome subincano, segmentis duobus intermediis basi utrinque albis. (23)

lugubris. 36. M. atra, albido-subpubescent; abdome segmentis intermediis basi utrinque, plantisque, albis; antennis thorace longioribus. (24)

sexnotata. 37. M. aterrima, pube incanâ; abdome segmentis tribus intermediis basi utrinque albis; alis apice nigris. (25)

* *. c.

Os linguâ acutiusculâ, auriculatâ, sæpius hastatâ, apice reflexâ.

Labium anticè obtusangulum, supra tuberculò munitum.

Femora postica flocculo instructa,

Anus fimbriatus.

Corpus villosum.

Obs. Mas absque flocculo atque fimbriâ.

Lathama. 38. M. atra, glabriuscula; abdome nigro, cingulo antico, ano, scopâque, rufis. (1)

Rosæ. 39. M. atra, cinereo-subvillosa; abdome cingulo antico rufo; scopâ versicolori. (2)

MONOGRAPHIA
APUM ANGLIÆ.

PARS QUARTA.

DESCRIPTIONES, SYNONYMA AUCTORUM,
MUSEA in quibus species heic descriptæ asservantur, necnon
OBSERVATIONES quasdam miscellaneas linguâ vernaculâ
scriptas, complexa.

En istæ sunt partes viarum ejus. Job.

O JEHOVA,
Omnia ista animantia in Te sperant
ut des illis escam tempore suo;
Te ipsis dante, illam colligunt,
aperiente MANUM Tuam satiantur bono;
Te recipiente spiritum eorum pereunt
et in pulverem revertantur;
Te emittente SPIRITUM Tuum creantur,
et renovas faciem terræ.
Gloria JEHOVÆ erit in seculæ
et lætatur JEHOVA operibus suis.
Canam JEHOVÆ in diebus vitæ meæ
reflectam SAPIENTIÆ Ejus radios, quandiu superero.
Benedic anima mea JEHOVÆ.
HALLELU-JAH. David.

DESCR. Acul.

CORPUS nigrum, pube albescenti.

CAPUT. *Facies* anticè pube, densâ admodum, albicanti, posticè fulvescenti, tecta. *Nasus* glabriusculus, ruguloso-punctulatus. *Antennæ* capitidis longitudine, nigræ.

TRUNCUS supra punctatus, pube fulvâ vestitus.

Squamulae nigro-piceæ. *Alæ* hyalinæ, nervis nigrican-

nigricantibus. *Pedes nigri, albido-pilosi, femoribus posticis hirtis.*

ABDOMEN fusco-nigrum, ovatum, acutum, supra valde convexum s. gibbum; segmento primo punctulatissimo glabro, secundo basi et apice, reliquis apice, latè tomentoso-niveis.

Maris *Antennæ* thoracis longitudine articulis arcuatis.

The *Melitta* here described, is the genuine *Apis succincta* of Linneus, as I find upon comparing it with the authentic specimen preserved in the Linnean cabinet: the rostrum, however, or proboscis, scarcely merits the epithet of *subulatum* which he has given to it. In the same cabinet there is another insect of this family, labelled by that great naturalist *Apis marginata*; this is much smaller than *M. succincta*, but in other respects it scarcely differs from it.

I have excluded the synonym of Geoffroy, referred to by Linneus for this insect, since it appears to me to belong rather to *Apis rotundata* of Fabricius. He places it next to *Apis longicornis*, and says of it "Cette abeille a beaucoup de rapport avec la précédente;" and again, "Le levre supérieure et le devant de la tête de l'insecte sont d'un jaune citron(a)." Both of which circumstances agree well with *A. rotundata*, but not at all with *M. succincta*. Gmelin and Villars refer to another

(a) Hist. Ins. Par. tom. 2. p. 413. n. 11.

synonym

synonym of this author for our insect, which I have likewise excluded, as to me it appears intended for the species that I shall next describe. That this species is Reaumur's Abeille "qui fait son nid de membranes soyeuses," appears evidently from a specimen of that insect which was sent by M. Latreille, the ingenious author of the work upon the Genera Insectorum noticed above (b), for my inspection, under the name of *Hylaeus glutinosus*. This specimen was rather smaller than ours, but there was no material difference between them.

Panzer's *Andrena succincta* (c) is very different from the true one; it appertains to another family of this genus, and seems very nearly related to *Melitta Swammerdamella*.

Linneus mentions the present species as very rare in Sweden; the aculeate sex has often been taken in the neighbourhood of London, but of the male I have seen only a single specimen, which is in the cabinet of Dr. Latham.

D

The

MELITTA. (*, a. b.)

The aculeate sex of this and the preceding species are extremely similar to each other; but the abdomen of *M. fodiens* is proportionally longer, more conical, and much less convex; it is also rather retuse at its base. The males, however, are more strikingly distinguished. I am a little dubious as to the synonym I have quoted from Geoffroy, but I think it ought to be referred to this rather than to *M. succincta*, on account of its nidificating under ground. His description will suit either equally well. Concerning the identity of Willughby's *Apis sylvestris in terra foramen sibi fodiens*, with our insect, I have scarcely any doubt.

DESCR. Acul.

CORPUS atrum.

CAPUT

CAPUT obscurum, punctulatissimum. *Antennæ* nigræ. *Frons* utrinque ad oculos maculâ luteâ.

TRUNCUS obscurus, punctulatissimus. *Squamulae* puncto albo notatae. *Alæ* subhyalinæ, nervis nigris. *Pedes* nigri, tibiis posticis basi luteo-albis.

ABDOMEN atrum, lucidum, parvâ pube parum canescens.

Var. β antennis subtus piceis; frontis maculis, tibiarumque annulo, flavis; tuberculis dimidiato-flavis.

γ frontis maculis obscurè ferrugineis; tuberculis puncto flavo.

δ antennis subtus fulvis; frontis maculis triangularibus, rufis.

ε antennis subtus obscurè rufescentibus; frontis maculis trapeziformibus, tuberculisque, flavis.

Maris *Antennæ* capite longiores, subtus obscurè fulvæ, scapo crassiusculo. *Facies* infra antennas lutea, punctis duobus nigricantibus. *Collare* utrinque strigâ albâ. *Plantæ* posticæ, interdum et intermediæ, basi albidæ. *Tibiæ* anteriores antrorsum rufescunt. *Abdomen* punctulatissimum.

Var. β fronte, tuberculisque, luteo-albis.

The insect I have here described agrees with the authentic specimens of *Apis annulata* in the Lin-

nean cabinet; indeed, several distinct species are there placed together as varieties of it, which Linneus appears to have regarded merely as such. Panzer's *Hylaeus annulatus* (*d*) is a very different insect, and belongs to a male of my third family of this genus. The observation of Fabricius upon his "*Moscham spirat*," proves its identity, at least with one of this family.

annularis. 4. *M. atra*; fronte maculata; tibiis omnibus flavo annulatis.

DESCR. Acul.

CORPUS atrum.

CAPUT subtriangulare, anticè truncatum, obscurum, punctulatissimum. *Antennæ* nigræ, subtus fulvæ. *Facies* maculis duabus flavis, antrorsum acutis, infra antennas notata.

TRUNCUS obscurus, punctulatissimus; tuberculæ, punctoque squamularum, flavis. *Pedes* atri, tibiis omnibus basi flavis.

ABDOMEN speciei hujusce abdomen præcedentis exactissimè refert.

(*d*) Fn. Ins. Germ. Init. n. 55. tab. 3.

Var.

Var. β fronte, macularum loco, punctis duobus obscuris, pallidis, notata.

Maris *Caput* anticè rotundatum. *Facies* infra *antennas* luteo-alba. *Antennæ* subtus dilutè fulvæ, scapo brevi conico. *Truncus* albidopilosulus, tuberculorum apice, tarsisque, albidis, tibiis luteis nigro annulatis.

Var. β maxillis albis, apice fuscis; tibiis anticis antrorsum rufis, digitis nigricantibus.

γ facie infra *antennas* pallidè rufesceni; nasi lateribus, antennisque nigris, scapo puncto flavescenti; tuberculis immaculatis; tibiis basi, anticis quatuor extrorsum, flavis; plantis flavescensibus; digitis obscurè ferrugineis.

δ facie maculis tribus distinctis, flavis; antennis subtus piceis, aliàs præcedenti simillimus.

This species appears to me to be very distinct from *M. annulata*: the head of the aculeates is rounder, and truncate before. The spots of the front, instead of being close to the eyes, are separated from them, and placed just below the base of the antennæ. All the tibiæ are yellow at their base. The scapus, also, of the antennæ of the males is shorter, and more conical.

5. *M. atra*; tibiis flavis, nigro annulatis; antennis *dilatata*.
scapo patelliformi.

DESCR. Mas.

CORPUS atrum.

CAPUT triangulare. *Maxillæ* albæ, apice fuscae.

Antennæ nigræ, subtus apiceque fulvæ; scapo dilatato, subquadrato, concavo-convexo s. patelliformi, dimidiato-luteo (e). *Facies* infra antennas alba.

TRUNCUS obscurus, punctulatissimus, cinerascenti-pilosulus; tuberculorum vertice, punc-toque squamularum, flavis. *Alæ* subhyalinæ, nervis nigris. *Pedes* flavi, femoribus, tibiarum posticarum annulo, anteriorumque quatuor maculâ, nigris.

ABDOMEN parvâ pube, vix conspicuâ, respersum.

The extraordinary size and shape of the scapus of the antennæ, which much resembles a Patella, will, I think, sufficiently justify me for considering this insect as a distinct species. Were this circumstance a sexual distinction only, the other males of the family would have it as well as this, which is not the case. I observed a variety of this insect in the Linnean cabinet with the dilated joint entirely black.

γ antennis subtus piceis, collare tuber-
culisque luteis.

Maris Corpus pilis brevissimis, albidis, subinca-
num. Facies infra antennas albida. Anten-
næ scapo crassiusculo.

This *Melitta* is larger than any of the preceding species of this family. It is entirely black, excepting only the underside of its antennæ, the spots on its front, a white fringe of short hairs on each side of the margin of the first dorsal segment of the abdomen, and its anterior tibiæ. Variety γ , appears to be *Vespa nigra, fronte thoracisque basi flavis* of Geoffroy, I am not certain that this may not be more than a variety. The aculeate sex of *M. annulata*, *annularis*, and *signata* have each a male agreeing with them in their peculiarities, a circumstance which furnishes a very strong proof that they are distinct species. On the other hand they all emit the same strong scent of balm, and are to be found usually on the same plants, viz. the different species of *Reseda*, to which they appear to confine themselves; this seems to indicate that they are only varieties. But when we consider that the same circumstances attach to *M. dilatata*, so remarkably distinguished from the other males by the shape of the scapus of its antennæ, I think we are warranted in concluding that they point out the habit of a family, rather than of a species.

Maris *Facies* anticè tomentoso-alba. *Antennæ*
submoni-

submoniliformes, thorace breviores, fusco-nigræ. *Abdomen* subovale, segmentis tribus ultimis nigris.

That this is the genuine *Nomada gibba* of Fabricius appears from the specimens labelled by him in the cabinet of Sir Joseph Banks, with which I formerly compared it. He observes, “*variat sexu abdomine toto rufo.*” I believe I possess the three sexes of this insect, but in all mine the anus is black. Amongst my exotic *Apes*, I have one which agrees with this description, but it is not at all related to *M. gibba*, though, at first sight, it somewhat resembles it. It is a genuine *Apis*, and seems to come near to *A. variegata*, but it has a singular labium, elongate, and I suppose, in its natural situation, inflected; gibbous at its base and shaped like an isosceles triangle, with the angle at the vertex somewhat rounded. Of how many joints its exterior palpi consist, I have not yet discovered. It may possibly be a connecting link between *Apis variegata*, and the family with an inflected lip. Scopoli says of his *Nomada succincta*, which is quoted, as synonymous with *M. gibba*, by Fabricius, and after him by Villars and Gmelin. “*Ceriferā vix minor, abdominis segmenta tria nigra sunt, margine tamen pallidè rufa. Nervi alarum majores pariter rufi.*” Circumstances which do not altogether agree with our insect. On this account I have added a mark of interrogation to this

this synonym. This species, in common with many others of the different families of this genus, is frequent in bare sunny banks. Reaumur found pupæ of three sizes in its cells (*f*) whence we may conjecture that it has three sexes. I take α to be the female, and the smaller variety β to be the neuter. From an examination of the proboscis of this species, this illustrious naturalist, as I observed above, and the Baron De Geer, were led to separate the genus, which they have called *Proabeille*, from *Apis*.

pilosus.

Geoffroy supposes this insect to be merely a variety of the preceding species, but the difference of size so far exceeds the limits which separate the sexes in this genus, that I cannot help regarding it as distinct. It differs likewise in the colour of its maxillæ, lip, antennæ, legs, and abdomen.

TRUNCUS. *Thorax* nitidus, glaber. *Squamulae* nigræ. *Alæ* infuscatæ, apice, nervisque, nigris; anastomosi ferrugineâ. *Pedes* atri, subpilosi, digitis rufescentibus.

ABDOMEN subovale, nitidum, segmento primo basi nigro, margine, duobus intermediis totis, antepenultimique basi, ferrugineis, reliquis nigris.

The species I have now described, very strongly resembles *M. gibba*; but the base, as well as the apex of the abdomen, is black. This part is also more oval, the lip is longer and triangular, and the wings have a black cloud at their tip. It is the genuine *Sphex gibba* of Linneus, as appears from the remains of the authentic specimen in the Linnean cabinet. I have excluded the synonym of Scopoli(g), since it is evidently intended for a different insect, nearly related to *Sphex viatica* and belonging to the Fabrician genus *Pompilus*. *M. sphecooides* appears to be the insect figured by Christius under the name of *Apis rufa*.

ε tertiam parte minor, abdomine nigro, cingulo angusto rufo.

Its black antennæ not so long as the thorax, and its short abdomen nearly oval, sufficiently distinguish this *Melitta* from the one just described, which it somewhat resembles. Its head and thorax likewise are not shining, which occasions a striking contrast between them and its lucid abdomen, on which account I have named it *divisa*. I am not clear that variety *γ* is not a distinct species, but as the only specimen I ever possessed of it was accidentally destroyed, unless I could have given it a more thorough examination, I thought it most adviseable to consider it as a variety. Varieties *δ* and *ε*, which are little more than half as big as *α*, may also be distinct, and are perhaps males of *M. Geoffrella*.

segmentis

segmentis margine latè tomentoso-albis, anticus interruptè. *Anus* et *Venter* pallido-hirti. *Máris Corpus* atrum, pube albidâ canescens. *Facies* infra antennas villoso-nivea. *Nasi apex* flavus. *Maxillæ* basi valde dilatatae (k). *Genæ* subtus concavæ. *Antennæ* thoracis longitudo, submoniliformes, fulvæ, supra basi fuscæ, scapo toto nigro, articulis extimis pellucidis. *Pedes* flavi, femoribus nigris, anterioribus quatuor antrorsum fulvo-flavis; tibiis posticis liturâ fuscâ. *Abdomen* lineare, ano obtuso. *Venter* anum versus depresso-f. concavus.

The male insect now described, appears evidently to be the *Hylæus quadricinctus* of Fabricius, and, I think, also *Apis*, n. 13. of Geoffroy, named by Fourcroy *A. hortensis*, although Villars has introduced them both into his work as distinct insects. The remarkably dilated maxillæ, and concave genæ, distinguish this sex of *M. quadricincta*, from the male of the following species, which it otherwise much resembles. I have never met with either sex of this insect in this part of England; but it has been taken, the aculeate sex twice by Dr. Latham, and the male once by Mr. Marsham, in the neighbourhood of London. I will not take upon me to assert positively, that these are the two sexes of the same individual species; but as they agree together as much as males and females in this family usually do, I thought it better to consider them as such,

γ cinereo-subpubescens; antennis subtus fulvescentibus: abdomine segmentis tribus anticis margine utrinque tomentoso-albis.
An eadem?

The aculeate sex of this species appears to be the *Apis rubicunda* of Christius, but I am not so certain that it is the *Apis flavipes* of Panzer; his figure agrees with it very well, but his description differs from it in some respects. Though very similar to the preceding species, it is certainly distinct; for its tarsi, the first pair excepted, and its posterior tibiæ, are not only covered with tawny hair, but their substance is likewise of the same colour; the down of the body also is rufescent, while

while that of the thorax is ferruginous. In the male, the differences are still more striking. The lip is yellow instead of black, the maxillæ are not dilated at their base (*l.*), the genæ are convex below. The antennæ and thighs are black. Variety β of the aculeate sex in nothing differs from α , except size, and the form of its abdomen, the base of which is narrower than the apex. It may be the neuter.

Var. β tibiis quatuor posticis strigā nigricanti, digitorum etiam articulus extimus nigrescit.

I have added a mark of interrogation to the synonym of Geoffroy, because he describes his specimens as having, the abdomen excepted, a black body; in other respects they appear to have been exactly similar to our insect. *M. flavipes* is not very unlike the *Apis tumulorum* of Linneus. Since the latter insect has been universally mistaken by entomologists for one of the *Euceræ* of Scopoli and Fabricius, (as I shall have occasion to observe more at large when I come to that family) it will not, I think, be unacceptable if I give a fuller description of it below, taken from the authentic specimens in the Linnean cabinet; thus future errors concerning it may be prevented (*m*).

δ minor, corpore atro, albescente-subviloso, labio nigro. Alias α similis.

ϵ tertia ferè parte minor, abdominis segmentis intermediis basi albis.

Variety γ of the aculeate sex of this insect, and variety δ of the male, may be distinct, but the differences appeared to me not striking enough to warrant my considering them as the sexes of a separate species. One of the varieties of the aculeates, I take to be the *Apis nitida* of the *Zoologia Danica*; but, since, after Fourcroy, I have given this name to another insect of this genus, I have distinguished this by another. Variety ϵ of the male, is,

is, I think, evidently the *Apis bicincta* of Schrank, but as his name harmonizes well with this variety only, I have not adopted it. Whether the *Hylaeus similis* of Fabricius (o) may not belong to a variety of this insect, I am not certain; but as I have as yet found none that will quite agree with his definition, I have not referred to it. Twice in the year 1799, in the month of August, in the evening, I found the males of this species, in considerable quantities, taking their repose upon the heads of the Ribwort Plantain.

29. M. atra, albido-subvillosa; abdomine segmentis intermediis rufis, fasciâ, punctisque lateralibus, nigris; labio flavo.

γ maxillis nigris; tibiis tantum basi luteis.
δ maxillis nigris, alarum nervis testaceis;
abdomine supra nigro segmentis margine late rufis, intermediis basi tomentoso-albis.

An eadem?

It is not without some hesitation that I give this as the *Hylæus albipes* of Fabricius; but, as he says of his, "variat interdum segmento secundo tertioque rufis, maculâ mediâ nigrâ," this variety may probably be our insect. The tibiæ, in all that I have had an opportunity of examining, have either a blackish

blackish cloud, which nearly surrounds their middle, or they are black with a yellowish base, as is the case with variety γ . Panzer's figure exactly resembles the insect here described, except that it omits the two black dots which distinguish each side of the abdomen; and, in his description, he makes no mention of the yellow lip. Variety δ , I suspect, may be a distinct species,

CAPUT obscurum. Facies infra antennas tomentosò-argentea. Nasus porrectus, apice flavus. Labium atrum. Antennæ nigræ, thoracem subæquantes.

TRUNCUS obscurus, punctulatus. Metathorax posticè subtruncatus. Squamulæ pallidæ. Alæ hyalinæ, apice paulò obscuriores, iricolores; nervis, costali interiori nigro excepto, ferrugineis. Tibiæ posticæ basi, Plantæque, luteo-albæ. Digiæ rufescunt.

ABDOMEN sublineare, apicem versus latius, nitidum, glabrum; segmento primo basi nigro, margine late, secundoque, rufis macula media trapeziformi nigra, tertio nigro lateribus rufis, ultimis nigris. Segmenta duo intermedia utrinque puncto nigro, itemque basi tomentoso-alba. *Venter* basi rufus litura semicirculari nigricante.

Var. β alarum nervis nigricantibus; tibiis immaculatis, plantis rufis basi albidis; abdomine segmentis margine rufis, secundo rufo macula magna dorsali, punctisque duobus lateralibus, nigris.

This insect is nearly related to the preceding species, but I think, with Panzer, we may venture to separate them. He, indeed, supposes that they may be different sexes of the same individual, but in this he is mistaken, as they are both certainly males, the female in this family being of a very different form. *M. abdominalis* is larger than *M. albipes*, its labium and maxillæ are black, the tibiæ also are black, the last pair only having a white ring at their base. The spots on the red segments of the abdomen are of a different form, and at the base of the three intermediate ones is a small patch of white decumbent hairs. Panzer's figure varies somewhat from our specimens; the margin of the intermediate segments of the abdomen in that being yellow, as well as the joints of the legs, which is not the case with ours.

Maris *Corpus* albescenti-incanum. *Antennæ* thorace breviores. *Facies* infra *antennas* tomentoso-argentea. *Nasus* apice albidus. *Alæ* valdè diaphanæ, iricolores. *Plantæ* quatuor posticæ albæ. *Digitorum* articulus extimus rufus, reliqui nigri. *Abdomen* sublineare, convexum, pilosulum.

This species a good deal resembles *M. laevigata*, but it is of a black still deeper. The pubescence of its whole body is cinereous. Its abdomen is punctulated, and the base of the intermediate segments are covered with decumbent hairs as white as snow. The wings of the male are beautifully transparent, not having their brightness obscured by the least shade of colour; at the same time, when the light falls upon them in a certain direction, they exhibit the hues of the rainbow. I think the aculeate

aculeate is beyond a doubt the *Apis leucozonia* of Schrank.

Var. β thoracis pube cinerascenti, plantis posticis quatuor albis.

This is one of the largest species of this family that we have in England, it may always be distinguished from all the rest by the colour of the posterior legs, which, the thighs excepted, are always red, and covered with reddish hair. I take this to be the insect which Christius has figured as the *Apis maxillosa* of Linneus, but it is certainly a widely different species. If I am right in my reference to him, the thorax of his specimen had lost all its ferruginous hair, an accident which not unfrequently happens to these insects. His *Apis emarginata*, likewise, very much resembles our insect (*p*), it may possibly be the male.

Variety α of this species, somewhat resembles *M. Lathamana*, but it is nevertheless very distinct. Not to mention the difference of their size, which is very considerable, *M. Rosæ* wants the ferruginous scopa and fimbria of the former. In the present family, the colour of the scopa affords an excellent character for the definition of species, as it is not subject to variation. I have defined it, upon the present occasion, and in several other instances, by the term *versicolor*, because, although the hairs of its upper side are of a different colour from those of

the under, yet, in certain lights, they appear wholly either of one colour or the other.

Had I known no other varieties than α and ϵ of *M. Rosæ*, I should, most probably, have regarded them as very distinct species; but by means of the intermediate ones, which exhibit the gradual change of the abdominal colours, their identity seems pretty clearly established; although I am still not without a suspicion, from the absence of the very minute tooth at the base of the maxillæ, which distinguishes α , β , and γ , whether δ and ϵ may not be more than varieties; unless we may suppose this to be a sexual distinction, and look upon α , β , and γ as females, and δ and ϵ as neufers.

The abdomen of α is distinguished by a red belt, which occupies the margin of the first, and the whole of the second and third segments; in β , the third segment is red only on the sides; in γ , the second also has a black spot in the middle; in δ , this spot becomes a fascia, extending nearly from side to side; and in ϵ , only the margin of the segments is red, and that sometimes very faintly. Through all these varieties the colour of the scopa remains the same.

Panzer's *Apis Rosæ* is evidently one of the varieties of our insect, but his description and figure are at variance. The former says, "abdomine — segmentis secundo, tertio, quandoque etiam primo posticè, rufis;" whereas, in the latter, the margin only

only of the first, and the whole of the second segment, are red, the latter having an intermediate blackish spot. This figure represents our variety γ .

Variety δ appears to be the insect which Christius has figured as the *Nomada cingulata* of Fabricius.

I have never met with any of the numerous varieties of this insect in my own neighbourhood; but it seems common enough, α and β excepted, in the vicinity of London.

It is without any hesitation that I give the two sexes of this insect as the *Nomada cingulata*, and *Andrena labiata* of Fabricius, since they exactly answer his description, except only that he does not take notice of the minute blackish spot on each side of the second abdominal segment, a circumstance easily overlooked. Panzer's figure, also, and description of his *Apis Sphegoides* and *albilabris*, accurately represent them, only he describes the hair of the legs of the former as yellow, which

is not the case with our specimens. It is remarkable that both Fabricius and Panzer, in this instance, apply the term labium, not to the tongue, which is the labium of the Fabrician system, nor yet to the Linnean labium, but to the anterior part of the face. The male agrees with the female in all such circumstances as the sexes usually possess in common, even so far as the black dot on each side of the second segment of the abdomen: a white or yellow nose is no uncommon characteristic of the male.

This

MELITTA. (*♀. e.)

This insect appears to be the *Andrena marginata* of Fabricius; when first taken I have sometimes found the whole abdomen red, but this colour in the three last segments assumes a blackish hue. The abdomen of his specimens he describes as ferruginous, in ours the two intermediate segments are of a pale red, and the whole abdomen is covered with down, which, if it be viewed from behind, gives it a reddish hue; the yellow hairs with which the margins of the last segments are fringed, in insects long disclosed will turn paler, Panzer's figure represents our insect with tolerable accuracy, only the thorax is too intensely red, Variety ♀, I suspect, may be the *Nomada Hattori-fiana* of Fabricius. As Schrank was the first describer of the species in question, under the name of *Apis Cetii*(q), I have named it after that ingenious entomologist.

Maris *Corpus* griseo-villosum. *Caput* hirsutum.

Antennæ thoracis longitudine, articulis arcuatâs. *Thorax* pilis subrufis longius villosus. *Abdomen* angustum, pilosulum.

M. albicans has usually been regarded in this country, as the *Apis helvola* of Linneus; upon this head

head I always entertained considerable doubts, and when I consulted the authentic specimen of that insect still preserved in the Linnean cabinet, I found that I was not mistaken, the true *A. helvolæ* being very distinct, as will appear hereafter. The definitions of the *Zoologia Danica* are so short, and unaccompanied by longer descriptions, that it is not always easy to say what insect is intended by them, but I think in my reference to that work upon this occasion I am not mistaken. Christius gives a figure of our insect as the *Andrena haemorrhoidalis* of Fabricius, which, however, is very different, it will be described in the course of this work. *M. albicans* is one of our most common *Melittæ.*

subnigris s. fuscis villosus. *Pedes* postici hir-
sutie nigrâ.

This Melitta has been described, under different names, by a variety of authors. It appears to be the *Apis atra* of Schrank, but not of Scopoli, the *Andrena pilipes* of Fabricius, the *Andrena aterrima* of Panzer, and the *Apis aterrima* and *cárbonaria* of Christius, for I take both these latter insects to be varieties of *M. pilipes*, the one with clouded and the other with unclouded wings; he does not, however, give the white scopa, which makes these synonymous

nonyms rather doubtful, they may be designed, however, for male insects. The synonym of Reaumur is dubious, since he says of his insect "les ailes sont d'un violet foncé," which is not the case with ours. Fabricius suspects that this species may be the *Apis retusa* of Linneus, but upon the authority of the Linnean cabinet I can venture to assert that it is very different from that insect. Indeed the principal character which this great naturalist selected to denote that species (*abdominis basi retusâ*) is not to be found in this.

When this little insect has loaded the hair upon the sides of its metathorax, and its posterior legs with pollen, the contrast between the sable hue of the animal and the whiteness of the pollen is very striking.

albido-cinereis parciūs villosum. *Anus* piloso-nigricans.

Obs. *In adulioribus thoracis pubes sordescit.*

M. pratensis much resembles the male of *M. tineraria*, but the hirsuties of its head is black, its abdomen is of a different form, and has no tinge of violet, and its wings are black at their tips. It has been long ago described in the *Zoologia Danica*. Fabricius gives it, if I am not mistaken in his insect, as the *A. carbonaria*, but that, as appears from the authentic specimen preserved in the Linnean cabinet, is very different, and indeed is no *Apis*, it seems to belong rather to the Fabrician genus *Scolia*.

subovatum, pilosulum.

I observed

I observed in the introductory part of the work(s), that Fabricius had placed the two sexes of this insect in two different genera. He appears to have been led to do this by the difference of their form, the male being much more slender than the other sex, without inspecting their instrumenta cibaria, which he would have found to be exactly alike. Christius has given the male for *A. thoracica*, and the female for *A. bicolor*. Panzer's figure of the male is extremely accurate. Variety β of the aculeate sex is common enough with us, but I never met with more than a single specimen of α , which appears to be the genuine *A. thoracica*, and that was given me by Mr. Marsham. They may be distinct species, but they are too similar to be separated, without a more striking difference than merely the colour of their wings.

This insect is often mistaken for the *Apis cunicularia* of Linneus: As such it is described by Miller in an interleaved copy of the *Systema Naturæ*, which belonged to the late Mr. Gray (so justly celebrated as the Pindar of our age) and contains several valuable descriptions and observations of that great genius, who was an excellent naturalist as well as poet. The following are Miller's words. “*Apis cunicularia. Mense Aprili frequens*

frequens in fossis sabulosis collium Hogmagog prope Cantabrigiam. Tota fusco-nigra, abdomine supra glabriuscule, nitente; thorace villoso fulvo-ferrugineo; macula alae marginali subfuscâ. Simillima *A. mellifica*." All the species of this family, at least so far as I am acquainted with them, excavate *cuniculi* for their little nests; and many of them, and among the rest *M. nitida*, have at first sight a considerable resemblance to the common hive bee; these circumstances occasion many different insects to be mistaken for *A. cunicularia*, Linneus has given no longer description of that insect, and his definition of it will agree with so many distinct species, that it is not to be wondered at, if this has generated errors. To prevent all future mistakes and confusion with respect to this insect, I shall give below a full description of it drawn from the authentic specimens preserved in the Linnean cabinet (*t.*).

Since the Linnean definition of this insect was intended principally to distinguish it from *A. mellifica*, which at first sight it much resembles, although when closely examined it will be found widely different; I have taken the liberty of altering it, so as to distinguish it from such of its congeners as will answer to that definition, and with which it is liable to be confounded. I have excluded all the synonyms usually referred to for it, as they may very probably belong to other insects. That of *Christius* evidently does. (p. 164. tab. 13. fig. 4.) I cannot find that this *Melitta* has ever been taken in England.

Obs. *Abdominis color nigro-æneus, tum hujus tum præcedentis speciei, ex pilis, qui tamen seorsum fulvescunt, exoritur; pilis enim abrasio, abdomen fit nigrum.*

This insect approaches nearer to the *Apis cunicularia* of Linneus, than any other English species with which I am acquainted: but it is sufficiently distinguished from it, by its black head and anus, and the form and colour of its abdomen. It is remarkable that the black abdomen should receive, from the tawney hairs which cover it, a nigro-æneous tinge.

Upon this insect I discovered, last spring, a very singular animal, which seems appropriated to the present

present genus. I had previously more than once observed upon other species something that I took to be a kind of *Acarus*, which appeared to be immoveably fixed just at the inosculations of the dorsal segments of the abdomen: at length, finding three or four upon a specimen of *M. nigro-aenea*, I determined not to lose that opportunity of taking one off to examine and describe; but what was my astonishment when upon my attempting to disengage it with a pin, I drew forth from the body of the *Melitta* a white, fleshy larva, a quarter of an inch in length; the head of which I had mistaken for an *Acarus* (*u*). How this animal receives its nourishment seems a mystery. Upon examining the head under a strong magnifier I could not discover any mouth or proboscis with which it might perforate the corneous covering of the abdomen, and so support itself by suction (*x*), on the under side of the head at its junction with the body there was a concavity (*y*); but I could observe nothing in this but a uniform, unbroken surface. As the body of the animal is inserted in the body of the *Melitta*, does that part receive its nutriment from it by absorption? My memory does not furnish me with any instance of this kind: but have the *vermes intestinales* any mouth?

After I had examined one specimen I attempted to extract a second, and the reader may imagine how greatly my astonishment was increased, when

- (*u*) Tab. 14. n. 11. fig. 7. and fig. 9. *a.* (*x*) Ibid fig. 8.
- (*y*) Ibid. fig. 7. *b.*

after

after I had drawn it out but a little way, I saw its skirt burst, and a head as black as ink, with large staring eyes and antennæ consisting of two branches, break forth, and move itself briskly from side to side. It looked like a little imp of darkness just emerging from the infernal regions. My eagerness to set free from its confinement this extraordinary animal may be easily conjectured. Indeed I was impatient to become better acquainted with so singular a creature. When it was completely disengaged, and I had secured it from making its escape, I set myself to examine it as accurately as possible; and I found, after a careful inquiry, that I had not only got a non-descript, but also an insect of a new genus, whose very class seemed dubious. From its mode of life it ought to belong to the Linnean genus *Ichneumon* in the *Hymenoptera*; but it has neither stemmata, nor four wings; and its palpi are not at all similar to those of the insects of that class(z). From its elytra, (which, however, are placed in a very extraordinary situation, being fixed to the sides of the thorax) it ought to be a *Coleopterous* insect, but it seems to possess but little of the general habit and character of that class: perhaps it had better be considered as *Hemipterous*, but till an opportunity occurs of examining more specimens it would be rash to speak too positively upon this head.

After I had sufficiently examined my animal, I made a rude sketch of it, its antennæ, &c. (a): and

(z) Tab. 14. n. 11. fig. 2 . a, b: and fig. 5. (a) Ibid. fig. 1—9.
it

it was well that I did, for upon leaving home for some weeks, when I returned, it was so miserably mauled by the great enemy of the entomologist, the *Acarus destructor* (*b*), that I should have been unable to give a tolerable idea of it, since both elytra and antennæ were gone: enough of it, however, still remains to shew what it was. I have not as yet met with another.

I shall attempt a description of it below (*c*)

TRUNCUS supra rufo-pubescent. *Squamule* piceæ. *Alæ* subhyalinæ, apice obscuriores; nervis, costali interiore nigro excepto, testaceis. *Pedes* rufescente-hirti, tarsis omnibus, tibiisque posticis, rufis.

ABDOMEN ovato-lanceolatum, hirtum.

Var. β major, maxillis basi dente obsoleto; thoracis hirsutie fulvâ; plantis quatuor anterioribus nigris; tibiis posticis apice tantum rufis.

This species resembles the male of the two preceding ones; from *M. Mouffetella*, however, it seems sufficiently distinguished by its black head; and from *M. nigro-aenea* by the colour of its tarsi, and the want of the black anus. I am not certain that variety *β* is not a distinct species, although of the same sex, it is much larger than *α*, and only the digitæ of the four anterior legs are red. The posterior tibiæ also are red only at their tips.

Pedes hirti. Scopulæ fulvæ.

ABDOMEN ovato-lanceolatum, hirtum. *Venter* basi utrinque maculâ magnâ, rufâ,

The red spot on each side of the base of the underside of the abdomen, and the black tarsi, are the principal characters which separate this species from *M. atriceps*, which, in other respects, it a good deal resembles. Indeed, the males of the different species in this genus are often so similar, that, where we are unacquainted with the other sex, it is not always easy to say which is a species and which a variety.

Trimmer-57. *M. nigra, grisescente-pubescent;* abdomine *ana.* hirsutulo; tibiis posticis scopâ versicolori.

Abdomen* ovato-lanceolatum, basi hirsuto-cinerascens, segmentis margine obscurè rufis.

This is the labelled *Apis helvola* of the Linnean cabinet; there are several specimens of the insect which I shall next describe placed by its side, which probably Linneus considered as nothing more than varieties of it. The description in the *Fauna Suecica* seems to have been taken from one of these; for the terms “*Abdomen nigricans minus villosum. Tibiae posticæ lanata ferruginea*,” will not agree with the genuine *A. helvola*, and vice versa, the last term of the nomen specificum in the *Systema Naturæ*, “*subtus albida*,” does not coincide with this supposed variety, which underneath is of a deep black. At first sight, the abdomen of this insect looks as if half the tawny hairs had been rubbed off, and only a patch of them left at its base; but this circumstance constantly attends the most recent individuals.

ABDOMEN lanceolatum, nitidum, pilosum; segmentis tribus anticis margine rufo-membranaceis.

Var. β minor, capite, respectu thoracis, minori; maxillis brevioribus; thoracis hirsutie sordidè griseâ.

This is one of the most singular insects of this genus that I have ever seen. Its long, forcipate maxillæ, and large black head, give it a very fero- cious aspect. The spine which arms the base of the maxillæ is, probably, only a sexual distinction. I do not find it described by any author; or if it be, the spines, its most striking characteristic, are overlooked. In Sir Joseph Banks's cabinet it stands as *Apis helvola*, it is the right-hand specimen.

armata. 64. M. nigra, cinerascente-villosa; maxillis longitudine capitis, basi dente armatis.

villosum, ano rufescente. *Venter* albido-hirtus.
Var. ♀ maxillis basi absque dente obsoleto; tho-
race, abdominalisque basi, hirsuto-ferrugineis,

M. subdentata is so similar to the preceding
species, that it is not without some hesitation that
I venture to separate them: but since they are both
of the same sex, the absence of the strong tooth at
the base of the maxillæ, and the long silver beard
which

which covers the anterior part of the face seem to indicate that they belong to different females. Variety β differs considerably from α , but I think not sufficiently to make another species of it.

DESCR. Acul.

CORPUS aterrimum, subhirsutum.

CAPUT. *Vertex calvus. Antennæ capite longiores, nigræ.*

TRUNCUS. *Thorax hirsutie densâ, ferrugineâ vestitus. Squamulæ ferrugineæ. Alæ hyalinæ, apice obscuriores; nervis ferrugineis, interoribus duobus nigris. Pedes atri, pilosissimi.*

ABDOMEN ovale, depresso, tergo pilis densis, fulvo-aureis, quasi per fascias hirsutissimo. Ani *Fimbria* pallidè flava. *Venter convexus, segmentis margine atro-hirtis.*

This is one of the most elegant of our English species of this genus, the deep orange of the thorax, and of the upper side of the abdomen, forming a most striking contrast with the intense black of the rest of the body. Led by the single circumstance of the thickness of its hirsuties, for I think there can be no doubt of this being his *Apis fulva*, Schrank has placed this amongst the *Bombinatrices*; as he has also *Apis rufa*, Lin., and *Apis pilipes*, Fab., but a very short examination would convince any

any entomologist that these are altogether distinct from that family. This is also the *A. vestita* of Fabricius and Panzer, and the latter has given a very accurate figure of it. Christius has likewise figured it under the name of *Apis vulpina*, and my friend Mr. Marsham has described it under that of *A. aurea*: his name I should have retained, as extremely apt, had not Schrank's had a prior claim.

Clarkella. 69. M. atra, hirsuta; thorace, pedibusque posticis, fulvis.

ABDOMEN ovatum, per fascias supra et infra atro-hirsutum.

In

In honorem D. Bracy Clark, Oestrorum monographi accuratissimi, nomen dedi.

Mr. Bracy Clark, author of a most ingenious paper upon the genus *Oestrus* in the third volume of the Transactions of the Linnean Society (*k*), sent me this *Melitta*, for the *Apis bicolor* of Fabricius. But that, as we have seen above, is only the male of *M. thoracica*; from this *M. Clarkella* is sufficiently distinguished by the hairiness of its abdomen, and the colour of its posterior legs. Christius has given us the figure of an *Apis*, which he names *A. icterica*, in colour much resembling our insect; but it is much smaller, and of a different form, I have therefore considerable doubts about its identity.

70. *M. nigra*, grisemente-subhirsuta; thorace ab-*Smithella* domineque hirsutis, fulvescentibus, segmentis margine albidioribus.

FIG. *Apis pilipes*. Panzer. Fn. Ins. Germ. Init. n. 7. tab. 13.

DESCR. Acul.

CORPUS nigrum, pube grisecenti.

(*k*) I would be understood to say this with the exception of his note containing the account of *Oestrus Cuniculi*: the opinion advanced in which, as militating against a superintending Providence, I think highly objectionable.

CAPUT. *Vertex calvus. Facies posticè pilis nigrantibus. Antennæ nigræ.*

TRUNCUS supra hirsutie, haud densâ, sordidè fulvâ. *Squamulæ nigræ. Alæ hyalinæ apice paulò obscuriores; nervis ferrugineis, duobus crassioribus nigris. Pedes griseo-pilosæ. Tibiæ posticæ scopâ versicolori, sub luce pallidâ, certo situ fuscescente. Scopulæ ferrugineæ. Flocculus pallidus.*

ABDOMEN subellipticum, subdepressum, hirsutum, hirsutie pro situ nunc fuscâ, nunc fulvescenti, segmentis margine pallidis. *Venter convexus, nitidus, segmentis infra marginem hirtis, marginis ciliâ brevissimâ, densâ, pallidâ.*

In honorem D. Præsidis Societatis Linnæanæ, Botanicorum principis, tum et in Entomologiâ peritissimi, nomen dedi.

Panzer, in an early number of his *Faunæ insectorum Germaniæ initia*, had figured the insect here described as the *Apis pilipes* of Fabricius; but afterwards he discovered that this was a mistake, and gives the real *A. pilipes*, but without substituting another name for this.

This insect and the preceding are liable to be confounded, since, upon a cursory view, there appears to be very little difference between them ; but if they be more closely examined, they will be found very distinct. The antennæ of *M. fuscipes* are entirely black, except only the under side of the two last joints ; its head is less hairy, and the hairs of the legs, and the scopa, which in the present family, in that respect, are not subject to vary, are brown. The vertex, in both these insects, is distinguished by a pale downy spot on each side adjoining to the eyes, scarcely to be discovered without the assistance of a magnifier, which seems designed to prevent the antennæ from receiving injury by friction : a circumstance which is observable in many other species.

76. *M. atra*, pallido-subvillosa ; abdomine segmentis margine albidis ; thoracis disco subpiloso, nigro.

L

ABDOMEN

ABDOMEN lanceolatum, convexum, albido-pilosum, segmentis apice obscurè rufescentibus. *Venter* albido per fascias hirtus.

A coloured nasus now and then distinguishes the males in this and the following genus. This we have seen before, in the instances of *M. cingulata*, *haemorrhoidalis*, and *chrysosceles*, as well as in the second family. I presume it is also a sexual character in the present and the following species. This has been taken only by my ingenious friend, the Rev. James Coyte of Ipswich, by whose name I have called it, and whose cabinet contains many other very rare insects.

labialis. 87. *M. nigra*, pallido-villosa; thorace fulvescenti; facie anticè albidâ; abdomine segmentis margine utrinque pallidis.

MUS. *D. Marsham, Trimmer, Kirby.*

Long. Corp. Lin. $5\frac{1}{2}$.

Hab. in Angliâ, capta saepius prope Londinum, semel juxta Norvicum.

DESCR. *Mas.*

CORPUS nigrum, pallido-villosum.

CAPUT trunco latius. *Os* albido-barbatum.

Facies posticè cinereo-villosa, anticè carneâ, naso punctulis duobus nigris. *Antennæ* nigræ, thorace breviores.

TRUNCUS. *Thorax* fulvescente-pubescent. *Squamulae* testaceæ. *Alæ* testaceæ, apice, nervo que costali interiore, nigricantibus. *Pedes* pallido-hirti, digitis ferrugineis. *Scopulae* fulvo-aureæ.

ABDOMEN

ABDOMEN lanceolato-ovatum; tergo ex pilis densis fusco-cinereo, segmentis utrinque margine albidioribus. *Venter* basi cinereo-subhirtus, segmento penultimo fimbriâ densâ, flavescenti.

Var. β thorace rufo; abdominis hirsutie grisecenti.

γ facie anticè flavâ.

88. M. nigra, pallido-villosa; thorace, tarsisque rufo-fuscis, utrinque strigâ albida. *Lewinella*.

CAPUT. *Facies* infra antennas hirsuto-grisescens.

Antennæ thorace breviores, piceo-nigræ.

TRUNCUS. *Thorax* pubes, haud densa, subgrisea
obsitus. *Squamulae* piceæ. *Alæ* hyalinæ,
iricolores, apice obscuriores; nervis nigrican-
tibus, anastomosi pallidæ. *Pedes* cinereo-hirti.
Scopulae fulvæ.

ABDOMEN ovatum, pilosulum, segmentis mar-
gine albo-ciliatis, anticis interruptè. *Venter*
cinereo-hirtus; segmentis margine fimbriâ
flavescente-nitenti ciliatis.

barbata. 90. M. nigra, lutecenti-villosa; abdomine subova-
to; segmentis margine membranaceis, albido-
ciliatis.

MUS. *D. Banks.*

Long. Corp. Lin. 4½.

Hab. in Angliâ.

DESCR. Mas.

CORPUS nigrum, pubes lutescenti.

CAPUT villis pallidis longius barbatum. *Facies*
hirsuto-lutescens.

TRUNCUS. *Alæ* subhyalinæ; nervis, excepto
costali interiore nigro, testaceis. *Pedes* albido-
hirti, digitis rufescentibus.

ABDOMEN

ABDOMEN fusco-nigrum, pallido-subvillosum ; segmentis anticis margine membranaceis, intermediis tribus albido-ciliatis, ultimis piloso-nigricantibus.

This insect, in the form of its abdomen, somewhat resembles *M. ovatula* ; its head, however, is extremely hairy, the margin of the anterior dorsal segments of the abdomen is membranaceous. The only specimen that I have ever seen of it is in the rich cabinet of Sir J. Banks.

91. *M. atra*, hirsuto-canescens ; abdomine lævi, *l*arbila-
lanceolato ; facie anticè barbâ densâ argenteâ. *b*rîs.

MUS. *D. Marsham*, *Sowerby*, *Kirby*.

Long. Corp. Lin. 4 $\frac{1}{2}$.

Hab. Barhamiæ in floribus mense Maio, e rarioribus una,

DESCR. Mas.

CORPUS atrum, hirsuto-încanum.

CAPUT. *Facies* anticè barbâ densâ, longâ, argenteo-nitidâ ornata. *Maxillæ* forcipatæ. *Antennæ* thorace breviores, nigræ.

TRUNCUS. *Thorax* hirsutie cinerascenti. *Squamulæ* nigræ. *Alæ* hyalinæ, apice paulò obscuriores; nervis piceis, anastomosi majusculâ. *Pedes* albido-hirti. *Scopulæ* pallidæ. *Digitæ* ferruginei.

ABDOMEN lanceolatum, acutum, piloso-subincanum, læve. *Venter* pilosulus, segmentis fimbriâ brevi, densâ, argenteâ, ciliatis.

This little insect is remarkable for the silver pile which is, as it were, combed over its mouth, and for the long hoary hair with which its body, the abdomen excepted, is thickly vested on all sides. In shape it resembles the *Andrena nitida* of Panzer (o), from which, however, it is very distinct.

barlatu- 92. M. atra, albido-villosa; abdomine subovali,
la. punctulato; segmentis intermediis margine
utrinque albis.

MUS. *D. Marsham, Trimmer, Kirby.*

Long. Corp. Lin. 4*l.*

Hab. Barhamiæ rario.

DESCR. Mas.

CORPUS atrum, albido-villosum.

CAPUT hirsutum. *Antennæ* thorace vix brevi-
ores, nigræ, nitidæ, articulis subarcuatis.

TRUNCUS. *Thorax* cinereo-pubescent. *Squa-
mulæ* nigræ. *Alæ* subhyalinæ, apice nigrin-
cantes; nervis, costali interiore nigro excepto,
ferrugineis. *Pedes* albido-hirti. *Scopulæ*
pallidæ.

ABDOMEN ex linearis-subovale; tergo punctulis
creberrimis levissimè impressis, nisi sub lente
vix conspicuis, perseminatum, segmentis tribus
intermediis utrinque ciliâ marginali albâ, basi
anoque viloso-albidis. *Venter* grisescente
subhirtus, segmentis ultimis ciliâ brevi, flaves-
centi, fimbriatis.

(*p.*) Tab. 4. **. c. fig. 9. a a.

nigricantes.

nigricantes. *Abdomen* ovato-lanceolatum, nitidum, basi rufescente villosulum; segmentorum ciliâ pallidâ.

Var. ♂ plantis omnibus nigris, corporis pube cinereâ.

This species varies much, but all the varieties here given are distinguished by a thick incurved fringe on each side of the metathorax, which these little creatures load with pollen. I am not clear, however, that ϵ is not distinct. *Apis combinata* of Christius appears to be a variety of our insect; if so, he has omitted the fringe of the metathorax. The male much resembles *M. Lewinella*, but in that all the tarsi are red.

95. *M. atra*, supra nudiuscula; metathorace utrinque, tibiisque posticis, pallido-lanatis.

MUS. Kirby.

Hab. In Suffolciâ, semel tantum lecta.

DESCR. Acul.

CORPUS atrum, subtus cinereo-villosum.

CAPUT subvillosum. Oculorum intervallum latissimum. Antennæ nigrae.

TRUNCUS. Thorax glabriusculus. Metathorax utrinque pallido-lanatus. Squamulæ piceæ. Alæ testaceæ, nervo costali interiore nigro. Pedes pallido-pilosi. Scopulæ fuscæ.

ABDOMEN subovale, basi et lateribus pilis longis admodum albidis subvillosum. Ani Fimbria rufescens. Venter per fascias cinereo-hirtus.

This

This species, in common with the preceding, possesses the fringe of the metathorax, although not so conspicuously. It wants, however, the dorsal fasciæ which invariably distinguish the abdomen of all the varieties of *M. combinata*, the place of which is supplied by a few long whitish hairs scattered over the base and sides of the abdomen of the insect before us. Its tarsi also are all black, and its thorax bare. This latter circumstance may be only accidental, for this part is very apt to have its hair rubbed off.

albicrus. 96. *M. atra*, cinereo-villosa; thorace fulvo; abdome ovato, pilosulo, strigis tribus albis; scopâ versicolori.

MUS. *D. Marsham, Trimmer, Louthbury, Kirby.*

M. minutula, *nana*, and *parvula* are very similar to each other, and extremely liable to be confounded; they are however distinct species, having each a peculiar male. *M. minutula* is less hairy than either of the others, the underside of its antennæ is more or less red, as are also its digitæ. From *M. nana* it is sufficiently distinguished, by having the surface of its abdomen impunctulate, and by its brown wings. The antennæ also of its male are proportionably shorter, than those of the same sex of that insect. Its silver scopa, and differently formed abdomen, evince its distinction from *M. parvula*. The innumerable punctula which, under a common magnifier, are visible upon the abdomen of *M. nana*, furnish a characteristic which well distinguishes

tinguishes it from the other two. And *M. parvula* may always be known by its short abdomen, and the cinereous hairs which cover its head and trunk. The hair upon the face of its male is black.

pilosula. 104. *M. nigra*, cinereo-subpilosa ; capite atro ; abdome subovali, segmentis margine membranaceis ; digitis ferrugineis.

MUS. *Kirby*.

vissimè impressis, pilis decumbentibus, brevis-
simis, rufescensibus, unde nudis oculis fuscum
esse videtur, conspersum, segmentis margine
pilis brevibus luteo-pallidis, anticis duobus in-
terruptè, ciliatis. Ani *Fimbria* densa, luteo-
pallida. Venter convexus, anum versus hirtus.

The

The abdomen of this species is more convex, both above and below, than is usual in the present family; a circumstance which sufficiently distinguishes it from any other.

107. *M. nigra, grisescente-subpubescens; thorace fuscata. fusco; abdomine ovato, convexiusculo, segmentis margine pallidis.*

MUS. Kirby.

Long. Corp: Lin. 4 $\frac{1}{2}$.

Hab. Barhamiæ, Maio medio 1800, in floribus lecta.

DESCR. Acul.

CORPUS nigrum, pube grisescenti.

CAPUT. *Facies* anticè fulvescente-villosa. *Ocipitis* pili fusi. *Antennæ* subtus piceo-nigræ.

TRUNCUS. *Thorax* nitidus, pube haud densâ fusco-nigricanti. *Squamulæ* nigræ. *Alæ* hyalinæ, apice paulò obscuriores; nervis, crassioribus nigris exceptis, anastomosique, ferrugineis. *Pedes* nigri, pallido pilosi. *Tibiæ* posticæ scopâ fulvâ.

ABDOMEN ex cordato subovatum, convexiusculum, glabrum; segmentis margine pallido ciliatis, anticis interruptè. Ani *Fimbria* rufescens.

M. fuscata, at first sight, might be mistaken for *M. convexiuscula*; but the down of the thorax is of a much darker hue, the posterior tibiæ and tarsi are black, the scopæ are tawny, and the abdomen is not so convex either above or below. Upon this

insect I found a *Pediculus*, nearly related to the *P. Apis* of Fabricius, but I think distinct, which I shall describe in the margin(s). The *P. Apis* is not uncommon upon the insects of this genus, I have found fourteen or fifteen upon the same individual; I have likewise frequently met with it upon genuine *Apes*. From Reaumur and De Geer we learn, that it also infests some individuals of the genus *Musca*(*t*); for it appears evident, that the hexapod, of which the latter author gives a long account as the larva of *Meloe Proscarabæus*, strange as it may seem, is no other than this insect. His description and figure tally with it exactly, not varying from the specimens I have examined in the slightest degree. This illustrious author, upon whose accuracy the greatest reliance may generally be placed, assures us, that from a mass of the eggs of this *Meloe* these larvæ proceeded; that he compared them with some he discovered upon *Musca*.

(*s*) *Melittæ*. *P. linearis*, niger; ore, tibiisque testaceis.

Long. Corp. Lin. $\frac{3}{4}$.

Hab. in Melittis semel lectus.

Major *P. Apum* et distinctus, *Corpus* angustum, lineare, nigrum. *Antennæ* biarticulatae setâ terminali. *Thorax* trium segmentorum. *Tibiae* *Tarsi* que pallidè testacei; hi ferè lanceiformes, exarticulati, utrinque setâ armati. *Anus* setis quatuor instructus exterioribus brevibus. Vid. Tab. 14. n. 11. fig. 10, 11, 12.

(*t*) Reaum. tom. 4. Mem. 11. p. 490. tab. 31. fig. 17.

De Geer. tom. 5. p. 8—12. tab. 1. fig. 5—8.

intricaria

Intricaria, Lin. and found them exactly the same; that he put a large fly or two amongst them, to which they attached themselves with the greatest avidity. Similar animals are mentioned to be hatched from these eggs both by Frisch and Goedart. Here seems to be an accumulation of evidence in confirmation of this extraordinary fact; and yet, to use De Geer's words, "Qui se seroit jamais imaginé, qu'on trouveroit les petits ou les larves des Cantharides de cette espèce sur le corps des Mouches? Jamais on ne se seroit avisé de les y chercher(*u*)."
Nothing seems more improbable than that a bee or a fly should afford nutriment to the larva of so large an animal as *Meloe Proscarabæus*, and that it should feed in the same manner as an *Acarus* or *Pediculus*. Its dimensions, one would think, if it was only a larva, would be found different in different individuals, according to their age; but this is not the case, for the animal in question varies scarcely at all in size. Can we suppose, that when it has attained to a certain size, it quits this kind of food for some other? All circumstances considered, I cannot help suspecting that there is some illusion in the case, which perhaps future observation will clear up.

Hab. in Angliâ, semel lecta.

DESCR. Acul.

CORPUS nigrum, cinereo-subpubescens.

CAPUT albicante-villosum. Linguae apex longior quam in praecedentibus. Auriculae minutæ. Palpi interiores vix fracti. Valvulae apice cultriformi. Antennae apice subtus rufopiceo. Stemmata in linea curva.

TRUNCUS. Thorax pube flavescenti tectus. Squamulae piceæ. Alæ hyalinæ, apice obscuriores, nervis nigricantibus. Pedes nigri, pallido-pilosæ. Tibiae posticæ scopâ certo situ argenteâ. Scopulae fulvescunt. Digitæ posteriores infra apicem plantæ inserti. Flacculus obsoletus.

ABDOMEN

MELITTA. (**. c.)

ABDOMEN ovatum, basi villosum et subretusum, segmentis tribus intermediis margine tomentoso-pallidis. Ani *Fimbria* medio atra, utrinque pallida. *Venter*, anum versus potissimum, cinereo-hirtus.

This and the following species vary from the characters of the insects of this genus, and approach to those of genuine *Apes*. Their tongue is longer with very minute auricles, and the tops of the valvulae are cultriform (*x*). They still, however, retain so much of the character of *Melitta*, as to be properly placed in that genus, and they will rank very well with the insects that compose the present family, with which they agree in habit. If considered as forming a distinct subdivision, it may be regarded as a connecting link between the genera which partakes of the characters of both.

TRUNCUS

TRUNCUS supra fulvo-pubescentis, thoracis disco pilis sparsis, atris consperso. *Squamulae* nigrae. *Ale* hyalinæ, apice nigricantes, nervis piceis. *Femora* pallido-barbata. *Tibiæ* rufo-pilosi. *Plantæ* extra pilis atris hirtæ, intus scopolis fulvis. *Tibiæ Plantæque* posticæ lanâ densâ, longissimâ, fulvâ, undique barbatæ(z). *Digitæ* articulo extimo rufo.

ABDOMEN subovale, atro-pubescentis; segmento primo viloso-pallido, proximis tribus margine tomentoso-niveis, anticis interruptè. Ani *Fimbria* densa, nigricans. *Venter* per fascias nigricante-pubescentis.

Maris *Corpus* supra pube densâ pallidè rufescens; subtus albescens, tectum. *Antennæ* vix thorace breviores, nigrae. *Pedes* hirti, postici elongati, plantis longius, sed haud dense, villosis. *Abdomen* ex lanceolato-ovatum, per fascias rufescente-hirsutum, segmentis margine albidiорibus.

This elegant insect has been long known, for it was in the collection of the celebrated Swammerdam, one of the fathers of Entomology, and has been tolerably figured by him. I have therefore decorated it with his name. Panzer has an admirable figure of it, under the name of *Andrena plumipes*, but in his description of it he says, “*Caput*

(z) Tab. 4. **. c. fig. 14.

nigro

nigro hirsutum—pedes flavo hirsuti—alæ hyalinæ, flavescentes." These circumstances do not agree with our specimens, which renders his synonym rather doubtful. He has figured the male as the *Apis farfarisequa* of Scopoli, in this I think he is mistaken.

No person at first sight would take the male and female of *M. Swammerdamella* for the same species, so widely do they differ in most particulars; nor should I have suspected that there was any connexion between them, had I not discovered their retreats. In the month of August, 1797, I saw a female take her flight from a grassy declivity of a southern aspect, which was much entangled with roots and shrubs. Upon examining this spot more narrowly, I discovered a number of small burrows, each of which had a little heap of sand, which had been excavated from it, lying before it. In some of these burrows I saw our *Melitta* sitting, with her head at the mouth, enjoying the sunshine; at the same time I observed many other insects flying about the spot. Upon my attempting to take them they disappeared, but they soon returned to their amusement. With some difficulty, I at length succeeded in taking one, and it proved to be the male just described. I have since frequently visited the same spot, and at the proper season have always found these insects there, both males and females, employed in the manner I have mentioned.

These

These circumstances convince me, that, though they differ so much in form and hirsuties, they are only the two sexes of the same species; especially since they agree in the shape of the tongue, which approaches very near to that of a genuine *Apis*.

 tibus flavisque variegatum. *Venter* ferrugi-
 neus, immaculatus.

This may probably be the other sex of one of the preceding species, for a ferruginous or red mouth is, in the present family, generally a characteristic of the aculeates, as a yellow one is of the males; but as the sexes usually agree as well in the ventral as in the dorsal markings of the abdomen, and in this respect *A. rufiventris* differs from them, I thought it best to consider it as distinct.

♂ facie rubore tantum bifurco; metathorace, tibiisque posticis, immaculatis.

♀ præcedenti similis, ventre ferrugineo, fasciis duabus, obscuris, flavis.

The following characters are constant through all the varieties of this Proteus species, namely the short horn upon the lip, which is easily seen under a common magnifier, if the head be viewed from one side, its ferruginous mouth and antennæ, its yellow collar, tubercles, squamulæ, and contiguous spots on the scutellum; and the ferruginous fascia of the first dorsal segment of the abdomen, which includes, and as it were insulates, two irregular yellow spots. When this insect is first taken it emits a very agreeable scent.

subcornu- 12. A. atra; labio subcornuto; abdominis ventre, maculisque tergi anticis, ferrugineis, posticis sex, anoque, flavis.

Facies infra antennas villose-argentea. *Antennæ* ferrugineaæ, supra basi dimidiato-nigræ, scapo antrorsum maculâ flavâ.

TRUNCUS. *Squamulæ* extrorsum pallidæ. *Scutellum* punctis duobus minutis, distantibus, flavis. *Alæ* subfuscæ, nervis nigris. *Pedes* ochracei femoribus rufis, subtus, apophysibusque, atris.

ABDOMEN subovatum, supra convexum, atrum, maculis sex per paria dispositis, anticis duabus minoribus, fasciisque tribus, flavis. Segmentum ultimum integrum. *Venter* anticè niger, posticè flavus et hirtus.

This species may possibly be the other sex of *A. Schæfferella*; I am induced to consider it as distinct by the following circumstances, in which it differs from that insect, and which seem more than sexual characters. The down of its head and trunk is white and thick for this family; its antennæ, on their upper side, are black from the base more

more than half way upwards; its tubercula are black, and the exterior margin of the squamulae is of a pale colour; the dots upon its scutellum are minute and distant; its tibiae and tarsi are yellow; the first pair of yellow spots upon the abdomen are smaller than the other two, and the last ventral segments are more hairy than is usual in the present family. Panzer's *Nomada sexfasciata* may, perhaps, be a variety of it; but, as I have doubts on that head, I have given it another trivial name.

20. A. atra; pedibus ferrugineis; scutelli punctis, *Jacobææ*.

mento secundo punctis duobus, tertio totidem utrinque, penultimo maculis binis dorsibus, luteis. An eadem?

Linneus regarded almost all the species that compose this family merely as varieties of his *A. ruficornis*; the one I have just described is particularly noticed by him as such in his Fauna Suecica, "Thorax niger, says he, "aliis lineæ ferrugineæ quatuor longitudinales." Terms which will exactly suit our insect; as in fact the thorax exhibits four ferruginous lines separated by three black ones, but as the ferruginous colour is predominant, I have reversed the characters. This insect stands with others in the Linnean cabinet under the above name. Induced by these circumstances, after Fabricius, I have selected this, from the rest, to give as *A. ruficornis*.

Panzer's figure of this insect is tolerably accurate, but in my copy the red parts are made too pale and glaring. It is a varying species, but may always be distinguished by its body variegated with black and red, in nearly equal proportions, and by the three black parallel lines inscribed upon the thorax. Variety ♂ differs considerably from the rest both in the form and markings of its abdomen, but as it agrees with them in these particulars, I have not considered it as distinct.

Revetti Sheppard, A.B. *juvenis ingenui, olim
discipuli mei dilecti, insectorum collectoris in-
defessi, oculatissimi, hæc Apis nomen gerit.*

This is the smallest species of this family with which I am, at present, acquainted; it is extremely similar in most respects to the preceding, and may,

possibly, be only a variety of it; but as its abdomen is only of one colour, without either red fascia, or yellow spots, besides slighter differences, I thought it most adviseable to give it as distinct.

TRUNCUS. Tubercula et Squamulae ferruginea. Scutellum tubercula duo valde elevata gerit. Alæ subhyalinæ, apice nervisque nigricantibus, lunulâ albâ. Pedes ferruginei, apophysibus, femoribusque posticis ferè totis, anterioribus quatuor subtus, tibiisque ultimi paris apice, nigris.

ABDOMEN

ABDOMEN subovatum, ferrugineum, basi, maculisque duabus anticis lateralibus, nigris. *Ani* extremitas truncata. *Venter* ferrugineus, segmentis omnibus basi fasciâ abbreviatâ nigrâ.

There is no authentic specimen of this species in the Linnean cabinet; what is now there as such was labelled by the present worthy possessor, but it answers the description of Linneus very well. The tubercula of this and the Linnean insect are yellow; in our specimen, which I owe to the liberality of Mr. Marsham, these are ferruginous. In other respects they agree together. Fabricius has omitted this species, perhaps he took it for a variety of *A. Fabriciella*, from which it is, however, extremely distinct. Forster introduces it into his catalogue of British insects. Panzer's *Nomada Germanica* comes very near to it, if it be not the same.

The horn upon the lip of this species seems to indicate that it ought to be placed near to *A. cornigera*, &c. but in habit and other respects, it appears to be more nearly related to those last described.

CORPUS nigrum, obscurum.

CAPUT albido-pilosulum. Maxillæ ferrugineæ.

Oculi, in vivo, incarnato-chrystallini. Antennæ piceo-nigræ. Facies circa basin antennarum tomentoso-argentea.

TRUNCUS glabriusculus. Collare utrinque tomentoso-lutescens. Thorax antice lineolis duabus

duabus tomentoso-lutescentibus inscriptus, posticè dentibus duobus ferrugineis, vix conspicuis, scutellum utrinque amplectentibus, armatus (*f*). *Tubercula, Scutellum, Squamulæ ferruginea.* *Metathorax* verticalis, utrinque maculâ tomentoso-nivcâ ornatus. *Pectus* circa pedum basin, item *Pleuræ* sub alis, tomentoso-alba. *Alæ* subhyalinæ apice nervisque nigris, lunulâ albâ. *Pedes* ferruginei, pilis brevissimis albidis subincani.

ABDOMEN basi subretusum, supra gibbum, segmento primo fasciis duabus interruptis, intermediis tribus maculis quatuor transversè positis, tomentoso-lacteis. *Venter* piceus.

Var. β femoribus posticis totis, intermediis subtus, piceis; abdomine segmenti secundi maculis in fasciam medio interruptam coalescentibus.

γ labio obscurè ferrugineo; thoracis dentibus atris; abdomine segmenti primi fasciis utrinque coalescentibus.

Our English specimens of this singularly pretty insect vary somewhat from the authentic *A. variegata* of the Linnean cabinet; for the scutellum of the latter is black, and it has more white hairs upon the anterior part of its thorax; it is, likewise, considerably smaller. In other respects they agree very well together. Panzer's *Nomada crucifera* is evidently nothing more than a casual variety of this

.(*f*) Tab. 6. **. b. fig. 9. *bb.*

Apis.

Apis. His figure does not give the teeth upon the posterior part of the thorax on each side of the scutellum, but these are easily overlooked. Christius's figure, of what he calls *A. variegata major*, belongs to an insect resembling *A. luctuosa*; but which is very different from the genuine *A. variegata*: his *A. muscaria* is a tolerable representation of it.

I first saw this bee in the cabinet of Mr. Drury, and afterwards found it, but by no means common, in the autumn of two succeeding years, 1797 and 1798, flying about sunny banks; since then I have not met with it.

ABDOMEN

ABDOMEN conicum, nitidum, segmento primo utrinque maculâ, reliquis margine, tomentoso-albidis. Segmentum ultimum lineâ longitudinali elevatusculâ. *Anus* acutissimus. *Venter* segmento primo maculâ mediâ; reliquis margine, tomentoso albidis, ultimo elongato, segmento anali dorsali longiore.

Var. β minor; corpore aterrimo; scutelli dentibus subobsoletis; alis vix nebulosis, nervis piceis anastomosi testacea; tibiarum spinulis testaceis; abdomine segmentis margine utrinque tomentoso-niveis.

Maris *Facies* pube densiore flavescenti, anticè pallidiori, tecta. *Alæ* nervis piceis. *Tibiae* spinulis ferrugineis. *Apophyses* anticæ articulo primo mucrone caput spectante instructo. *Abdomen* segmento primo utrinque, proximis tribus margine, tomentoso-pallidis, ultimo quadridentato dentibus intermediis furcatis (i).

Venter segmentis margine tomentoso-albidis.

Var. β minor, abdomine segmentis utrinque margine tomentoso-albis; ano sexdentato.

γ minor; corporis pube albâ; abdomine segmentis tam ventralibus quam dorsalibus utrinque margine tomentoso-niveis; ano sexdentato.

Obs. *In his varietatibus abdominis segmentum penultimum utrinque dente minuto instructum.*

(i) Tab. 7. fig. 13, 14.

I observed

I observed above (*k*), that *A. conica* and *quadridentata* were male and female, it will perhaps be expected that I should here assign the reasons which induced me to adopt this opinion.

Any one who compares these two insects together, will immediately perceive between them the most striking resemblance, and that the only difference arises from the anal spines or teeth, and more thickly coated face of *A. quadridentata*. Now as these circumstances are common distinctions of the male sex in all the subdivisions of this family, they will not furnish a sufficient reason for separating insects which are so very similar in other respects, without specimens of each sex can be produced, distinguished in one instance by an acute anus, and in the other armed with anal spines; but as those which exhibit the former character are invariably aculeates, and those that possess the latter as invariably males, I think this alone will sufficiently justify me for putting them together. Rossi, although apparently not aware of the difference of sex of these two insects, seems to think *A. quadridentata* a variety of *A. conica*. "Alia," says he, under *A. conica*, "præterea specimina habemus, statu et habitu omnino prioribus simillima, quæ cum habeant abdomen conicum, atrum, marginibus incisurarum quinque albis, anum quadridentatum dentibus intermediis bifidis, *A. quadridentata* nomine determinari possent."

(*k*) Vol. 1. p. 153.

VOL. II.

a

In

In confirmation of the above opinion, I have been informed by Mr. James Trimmer, so frequently mentioned in these pages, that he has often observed *A. quadridentata* attendant upon *A. conica*.

The authentic specimen of *A. conica* preserved in the Linnean cabinet has teeth upon its scutellum, and, therefore, that which Fabricius has given as such, "scutello inermi," is another insect, and probably the aculeate of that which I shall next describe. To this I have referred also the synonyms of Gmelin and Rossi for the same reason. Panzer's *A. bidentata* is the Linnean *A. conica*. Linneus has described *A. quadridentata* "cingulis quinis albidis," all my specimens have only four white bands, the first of which is interrupted: Panzer's figure however answers the Linnean character in this respect, and Rossi notices the same circumstance. Probably the down upon the margin of the last segment but one is liable to be rubbed off.

There are three synonyms to which reference is usually made for the sexes of *A. conica*, which have no relation to that species. The first is that of Ray (*l*), which belongs either to a *Sphecius*, or a male of my family of *Apis*. *. b.. perhaps to *A. Goodeniana*. The next is that of Reaumur (*m*), (which, as I observed above, is the male of one of the leaf

(*l*) Rai. Hist. Ins. p. 252. n. ult.

(*m*) Tom. 6. tab. 11. fig. 2, 3, 4.

cutters,

cutters, with a quadridentate anus), to which Linneus referred as synonymous with *A. conica*, it is probable, from a hasty view of the figure which somewhat resembles that insect. The last is that of Swammerdam (*n*), whose figure is quoted by Linneus and others after him both as *A. quadridentata* and *A. manicata*; but the figure, although a bad one, evidently belongs to the latter insect.

Variety β of the aculeate sex, and γ of the male, may be the sexes of a distinct species, but they so nearly resemble the others that, without fuller evidence, I was unwilling to separate them.

DESCR.

DESCR. Mas.

CORPUS atrum, pube albidâ canescens, punctulis excavatis quasi granulatum.

CAPUT. *Facies* ante antennas pube cinerascenti tecta. *Oculi* pilosi.

TRUNCUS. *Scutellum* inerme. *Squamulae* atræ.

Alæ fuscescentes, nebulosæ, apice obscuriores, nervis nigris anastomosi ferrugineâ. *Pedes* pilosuli, tibiarum spinulis testaceis. *Apophyses* anticæ articulo primo antrorsum mucronato.

ABDOMEN lineare, subcylindricum (*n*), cingulis quatuor tomentoso-niveis, supra interruptis infra continuis, ano quadridentato dentibus intermediis furcatis, segmento penultimo dente marginali utrinque instructo.

I have not yet met with the aculeate sex of this species, but I do not hesitate to give it as the *A. conica* of Fabricius, Gmelin, and Rossi, although not of Linneus. The circumstance which principally distinguishes it from the preceding species, is the absence of the tooth on each side of the scutellum, which constantly attends all the varieties of that insect. The abdomen of the male is likewise of a different form, and its dorsal white fasciæ are interrupted. Miller, in Mr. Gray's interleaved edition of the *Systema Naturæ*, has described an insect as *A. quadridentata*, very similar to the male of our *A. inermis*, if it be not the same, in these

I am led to give *A. Willughbiella* as the Willow Bee, whose history and economy so attracted the attention of the English Naturalists of the last century, by the circumstance of its having been most commonly taken in places abounding with willow trees. I find it in Barham in some low meadows which are surrounded with them; it is also frequently met with at Brentford, and other places near the Thames.

I have not hitherto been successful enough to meet with its nidus, so as to ascertain whether what I have given as the sexes come from the same, but they agree together in such particulars as the sexes usually do, and are found in the same situations, and therefore I feel no great doubt concerning their identity. Sir John Hill, in his translation of Swammerdam's Book of Nature, in a note, says, that he has seen thousands of the nests of these bees in Lincolnshire (y); it is probable that where they so abound, they must do considerable injury to the trees in question.

(y) Hill's Swammerdam, P. 1. p. 227. Note *.

The

The male of *A. Willughbiella* is very like *A. Lagopoda* of Linneus, and is often mistaken for it; but it is extremely distinct from the authentic specimen still preserved in the Linnean cabinet; the singular conformation of the tarsus of the fore feet, which is given as the most prominent characteristic of *A. Lagopoda*, is common, as I observed before (z) to many distinct species, and is only a sexual character. This sex of our insect exhibits a peculiarity, which none of those that are related to it in the form of the anterior tarsus, possess, the last joint of its antennæ is larger than any of the rest, which gives them some resemblance to those of a *Papilio* (a), in *A. Lagopoda, bidentata*, and its other affinities, they are filiform. That this class of males may no longer be confounded with *A. Lagopoda* I shall insert in the margin a new description of that insect, taken from the authentic specimen (b).

ABDOMEN subrotundum, basi depresso, griseo-subhirsutum. Anus emarginatus lobis denticulatis.

I am not certain whether the mucro observable on the first joint of the anterior apophyses of the male of *A. Willughbiella*, exists in *A. lagopoda* or not; when the above description was drawn out, I had not observed it in the former, therefore it is very probable I might overlook it in the latter.

The insect which Schrank (*a*) and Panzer (*b*) have given as *A. lagopoda* is different from it, and likewise from *A. Willughbiella*, but it appears to agree with an unlabelled specimen in the Linnean cabinet, which is placed with the former as a variety, but which is much smaller, not so hairy, with posterior tibiae proportionably less. The figures of Sulzer (*c*) and Christius (*d*) have no relation whatever to any of these males. I possess a foreign specimen of one, given me by the ingenious Mr. Sowerby, which exhibits the same peculiar structure of the anterior tarsus, and is extremely distinct from all the

Venter planiusculus, segmentis margine pilis
albidis ciliatis.

This *Apis* is considerably smaller than the preceding, the abdomen of the aculeates is proportionally longer and narrower, and the margin of its dorsal segments is fringed on each side with white or yellowish hairs; the anus also has no black hairs. The male is still more strikingly distinguished from the same sex of *A. Willughbiella*, for it wants the dilated anterior tarsus, its antennæ are filiform, its maxillæ are armed at the apex with two teeth only, of which the interior is truncate and very short, its primary apophyses have no mucro upon their first joint, and its anus is entire.

The specimens labelled as *A. centuncularis* in the Linnean cabinet, do not agree with the description of that insect given in the *Fauna Suecica*. "Abdomen ovatum, nigrum, acutum, incisatum marginibus albis." In those specimens the

(c) Tab. 8. fig. 12.

(d) Ibid. fig. 25.

margin

margin of the abdominal segments has no white hairs, nor is the anus particularly acute, they appear to me to be the other sex of the genuine *A. lagopoda*. It is probable that Linneus, looking upon all the leaf cutter Bees as varieties only of the same species, was not particular in the selection of the specimens he preserved. Reaumur's figure and description agree with our insect, but those that he was acquainted with made their nests underground. Geoffroy represents his as nidificating in old wood, and the trunks of decayed trees. Mr. James Trimmer found the nest of ours in a decaying window-sell, and likewise in the cavity of a brick wall. He observed that this little bee made use of the leaves of *Mercurialis annua*, as well as those of the rose. Perhaps it is indifferent to this animal where she constructs her centunculi, provided it be in a place sufficiently sheltered from the weather. The insect which Scopoli took for *A. centuncularis* appears to me to be very distinct from it, he describes it as much smaller, and the thorax as covered with thick red hair (*e*), a circumstance which will not at all agree with ours. The synonym of Ray (*f*), which I have likewise excluded, evidently belongs to another insect, the terms "parva, corpore longo angusto," cannot well be looked upon as descriptive of *A. centuncularis*.

(h) Tab. 8. fig. 13: (i) Ibid. fig. 19.

tusiusculus.

tusiusculus. Venter anticè lanâ fulvâ, posticè fuscâ, tectus.

This insect is distinguished, from those that precede it, by the size of its maxillæ, which are unusually large and prominent, and scarcely, if at all, forcipate; the teeth at their tips are most of them rounded, none being acute, as in the others; the abdomen, also, is of a different shape. Panzer has figured a maxilla as belonging to the other sex of his *A. centuncularis* (*k*), which represents well the same part of *A. maritima*. It is certainly not the maxilla of a male, and his figure is that of an aculeate, whence it follows that it belongs to another species.

44. *A. griseo-pubescent;* abdomine *femineo sub-ligniseca,* ovali; *masculo subgloboso, ano emarginato.*

DESCR.

DESCR. Acul.

CORPUS nigrum, pube grisescenti.

CAPUT. *Maxillæ* prominentes, validæ, forcipatæ, apice quadridentatae, dentibus exteris duobus acutis, intermedio truncato, intimo emarginato (*l*). *Antennæ* capitidis ferè longitudine, nigræ.

TRUNCUS supra villis sordidè fulvis tecta, disci pube rariore nigricanti, *Squamulæ* nigræ. *Ale* subhyalinæ, apice obscuriores, nervis nigris. *Pedes* hirti, tibiarum spinulis ferrugineis. *Scopulæ* fulvo-aureæ.

ABDOMEN ex oblongo ovale (*m*), anticè cinereo-subvillosum, posticè pilis nigris consitum. *Anus* obtusiusculus. *Venter* lanâ fulvâ vestitus.

Var. β ventris lanâ, anum versus, nigrâ.

Maris *Corpus* longius et densius villosum. *Facies* ante antennas barbâ densâ flavescenti. *Antennæ* thorace breviores. *Thorax* pube flavescenti. *Abdomen* ex oblongo globosum, flavescenti vellere lanuginosum, ano inflexo, emarginato (*n*).

Var. β corporis hirsutie cinerascenti; digitis articulo extimo ferrugineo.

This insect has been figured as *A. centuncularis* by Panzer and the ingenious Mr. Donovan, it is, however, very distinct from it; for it is not only

(*l*) Tab. 8. fig. 14. (*m*) Ibid. fig. 21. (*n*) Ibid. fig. 25.
considerably

considerably larger, but the abdomen of the aculeates instead of being cordate is oval, and its dorsal segments have no white marginal fringe. The anus also of the males is emarginate. The last mentioned author informs us that *A. ligniseca* commits great ravages in oak plantations; trees of that kind, apparently healthy, at Birdbrook in Essex, being completely perforated by it, and filled with its centunculi: but it does not confine itself solely to the oak, for upon the tenth of September, 1799, upon observing a bee belonging to the present subdivision enter the trunk of a putrescent elm, I obtained leave to take the tree down; upon opening it, I discovered, in the center, the nest, and also one of the bees, which proved to be the one now before us. The nest was made of elm leaves, each cell was about an inch and a quarter in length, and not quite half an inch in diameter; a circumstance which furnishes an additional proof that this insect is distinct from *A. centuncularis*, for the cells of the latter are not an inch in length, and scarcely the fourth of an inch in diameter. The tree which *A. ligniseca* had selected to contain her nest, was beginning to decay at the heart, here she had bored a channel whose diameter was adapted to that necessary for her cells, the direction of which was according to the state of the wood at the center, following the putrescent vein. Plot, in his history of Staffordshire, makes mention of one of these bees as constructing its nest in a decaying crab tree.

This insect departs somewhat from the general habit of this subdivision, the upper side of the abdomen being convex, instead of flat; it seems to approach very near to Geoffroy's "Abeille maçonne à poils roux;" but as he describes his as having tawny hairs upon its head and legs, which is not the case with ours, I have added a mark of interrogation to his synonym: My specimen, the only one I ever saw, I took creeping upon a clay bank of a southern aspect, not in the neighbourhood of any wall.

ABDOMEN supra subvillosum, punctulatum, segmentis utrinque puncto flavo notatis. Segmentum antepenultimum punctis flavis quatuor. Abdominis latera flavo-ciliata. *Anus* obsoletè trilobus, incurvus. *Venter* lanâ pallidâ tectus.

Var. β occidente punctis flavis nullis; tibiis anticis basi apiceque flavis; abdomine seg-

(q) Tab. 9. 2. β. fig. 6.

mento antepenultimo maculis tantum duabus mediis flavis.

Maris Maxillæ apice tridentatæ (r). *Facies* ante *antennas* flava *maculâ posticâ mediâ nigrâ*. *Pedes* albido-hirti. *Femora nigra*, apice sub-tus dente obtuso utrinque instructa. *Tibiæ* quatuor anteriores apice flavæ, cunctæ subtus barbâ densâ albâ. *Plantæ* albo hirsutissimæ. *Palmæ* flavæ. *Apophyses* posticæ articulo secundo intus obtusangulo (s). *Abdomen* ciliâ densâ, incurvâ, pallidâ utrinque ornatum, segmento penultimo maculis duabus sublunatis flavis picto, utrinque spinâ incurvâ armato (t), ultimo spinis tribus incurvis instructo, inter-medio recto breviori, lateralibus divaricatis (u). *Anus* sëpe valde inflexus.

Obs. *Abdominis segmenta intermedia in angulum f. dentem obtusum protensa* (x). *Plantæ inter-dum flavæ*.

Linneus in his definition of this insect seems to have overlooked the spines which arm the last segment but one of the abdomen of the male; for instead of being tridentate the anus is in fact quin-quedentate. This error has been rectified by Fabricius. The synonym of Swammerdam evidently belongs to *A. manicata*, and not to *A. quadriden-tata*, for the dorsal spots of the abdomen, and five

spines

spines of the anus, are plainly represented in his figure. Geoffroy has mistaken the male for the female, and Panzer has fallen into the same error, that which he has given as the male is a distinct species. Anal spines or teeth in this family are invariably a sexual distinction, and point out the males.

This singular insect may always be known by its prominent maxillæ, which when closed leave a space between themselves and the mouth, which space is filled by the hairs with which their inner side is bearded; its lip is also remarkably elongate. Panzer has given an admirable figure of it; that of Christius belongs to some other insect. We learn from Mr. Marsham that *A. maxillosa* is the prey of *Ichneumon manifestator*, and from Bergman that *I. jaculator* pierces this as well as *A. florisonnis*, which indeed I strongly suspect to be its male. Nor are these the only insects of that genus to the attacks of which our *Apis* is exposed, for Mr. J. Trimmer has taken another out of its foramina, which, as it appears to be a non-descript, and

tennæ

tænnæ jutting out on their under side into an obtuse angle, the remarkable horn or protuberance which arms the base of the venter, the cavity which answers to it, and into which, when the insect reposes in its flowery bed, it is probably inserted, and the teeth which terminate its anus on the underside, are peculiarities, which I do not recollect that any preceding author has noticed, but which strikingly distinguish this insect. All of these however I take to be sexual distinctions, for this insect is always male and the preceding is as invariably of the other sex, a circumstance, which, combined with general traits of resemblance, makes me suspect that they are only the sexes of the same species. The spines at the apex of the tibiæ, which Linneus has introduced into his definition, are not more conspicuous in this, than in the other species of the genus; Fabricius has therefore very properly omitted them in his character.

Schæffer has written a monograph in German upon an *Apis*, which he calls *A. florisomnis* (g), but which is, in fact, a very different species. He describes it as distinguished by a very particular circumstance, namely, antennæ involute or turned in at their tips. His figure represents an insect quite distinct from ours, it may possibly, be the

Maris

Maris Corpus cinereo-vilosulum. Antennæ filiformes, capite longiores (k). Facies ante antennas niveo-vilosula. Abdomen inflexum ano acutè bidentato (l). Venter segmento secundo tuberculo elevatusculo munito (m), cui ex adverso opponitur apud anum cavitas rotunda, tomentoso-pallida.

This little Apis, by far the most minute species of this genus, that I have yet seen, is common, during the summer and autumnal months, in the blossoms of *Campanula Trachelium, rotundifolia*, and *hybrida*, and, what deserves to be remarked, I never found it in the flowers of any other genus of plants. The males are often taken asleep in these flowers, their abdomen is then doubled, so that the tubercle, with which its base is armed, fits into the cavity near the anus. The aculeates partake of the habit of *A. maxillosa*, and the males in the same degree resemble *A. florisonnis*, a further proof of the identity of those insects. I have never met with this insect in any other situation than the above, and therefore I can say nothing further with respect to their mode of nidification, than that it is most probable that, with the other species of this subdivision, they make their cells in posts, rails, and the like. The male of *A. campanularum* is, I think beyond a doubt, the *A. florisonnis minima* of Christius.

Two or three distinct insects are placed together, in the Linnean cabinet, as *A. truncorum*, the one I have just described is the same with the labelled specimen. Linneus says, in his Fauna Suecica, "Antennæ longitudine thoracis. Abdominis segmenta vix margine albâ, sed potius versus latera." But in the above specimen, and our English one, the antennæ are only a little longer than the head; and the whole margin of the abdominal segments is fringed with white hairs; this description was probably made from one, part of whose hairs had

been rubbed off, an accident to which these animals are very subject. Christius has given an *A. truncorum*, but it is a very different insect. Panzer's figure is tolerably accurate, he has made the tip of the wings rather too dark. The synonym of Fabricius seems to me rather dubious, for he says of his "abdomine—subtus cinereo-hirsuto," which is not the case with *A. truncorum*; in a specimen long disclosed, however, the hairs on the underside of the abdomen might turn to cinereous; and Panzer observes upon this species "variat abdominis lanâ subtus cinerea et flavâ."

ABDOMEN ex ovali sublineare, supra glabriusculum, segmentis anticus quatuor margine utrinque pilis niveis ciliatis, primo et secundo apice auctis. *Venter lanâ haud densâ cinereâ* mollis.

This species, although very distinct from it, is very liable, at first sight, to be confounded with *A. truncorum*. If its proboscis be not unfolded; so that the palpi can be examined, it may always be known by the absence of the elevated curved line, which is observable upon the first segment of the abdomen of both sexes of the latter insect. It may possibly be the *Hylaeus truncorum* of Fabricius. I look upon this insect as forming the connecting link which unites the present with the preceding subdivision.

CORPUS atrum, punctulatissimum, pube grisecenti.

CAPUT magnum. *Maxillæ* vix forcipatæ, apice tridentatæ, dente interiori truncato, exterioribus duobus acutis, disco supra tomento aureo tecto. *Antennæ* nigræ, capitis longitidine. *Facies* satis hirta.

TRUNCUS. *Squamulæ* nigræ. *Alæ* fuscæ, albidio subnebulosæ, nervis nigris. *Pedes* rufescente-pilosi. *Scopulæ* ferrugineæ. *Spinulæ* nigræ.

ABDOMEN ex oblongo cordatum, atro-cærulescens, basi subretusum, supra subglabrum, nitidissimum.

nitidissimum. Pili rufi, haud densi, segmentorum margines, anticorum interruptè, firmant. *Anus* incurvus, rufo-subtomentosus. *Venter* lanâ densâ ferrugineâ tectus.

Var. β dimidio minor; abdomine nigro-æneo.

γ corporis hirsutie cinerea; abdomine aterrimo, segmentis margine derasis. *An eadem?*

In honorem D. A. Mac Leay, Soc. Linnæan. a Secretis, *viri amicissimi, Naturæ regna, et imprimis Entomologiam, summo judicio et acumine perlustrantis, hoc insectum nominavi.*

This insect agrees tolerably well with Geoffroy's description of his "Abeille fauve à ventre cuivreux," except that the hair of the body can scarcely be called red. Since both Fabricius and Schrank have an *Apis hirta*, I have altered Fourcroy's trivial name. Variety *γ* may, perhaps, be a distinct species; but upon the whole it so strongly resembles *α*, that I have not ventured to separate them.

cærules- 55. A. corpore *femineo* atro, albido-subpubescens; *cens.* abdomine cærulescenti, segmentis margine albicantibus, ventre lanâ atrâ: corpore *masculo* æneo, fulvo-pubescente; ano bidentato.

(*p*) Tab. 10. c. 2. 3. fig. 19. *aa.*

two

two insects, which, at first sight, appear so extremely unlike each other, as *A. cærulescens* and *A. ænea*. The authority of the Baron de Geer will have great weight with every entomologist, and he informs us that he took both these insects out of the same nidus. These are his words, “ Les abeilles, que je tirai de ces coques et qui n'étoient gueres plus grandes que des mouches domestiques, étoient de deux couleurs ; les unes d'un bleu violet foncé et comme noirâtre, mais luisant, ayant les yeux noirs, et la tête et le corps couverts de poils cendrés et blanchâtres. Les autres abeilles avoient le fond de la tête, de tout le corps et des pattes d'un verd foncé, bronzé et luisant ; mais toutes ces parties, en particulier le corcelet, étoient couvertes de beaucoup de poils roux, qui sur le ventre n'étoient cependant placés que de chaque côté et le long de bord postérieur de chaque anneau, et ces poils formoient sur le ventre du mâle comme des rayes transversales rousses, tandis qu'en dessous il étoit tout ras. Les antennes étoient noires et les yeux à réseau d'un verd clair. J'ai lieu de croire, que les abeilles bleues étoient les femelles, et les vertes les mâles, puisque ces derniers étoient un peu plus petits que les autres (q)”

This account sufficiently proves his insects to be only different sexes of the same species, and that ours are synonymous with his will appear evidently

(q) Tom. 2. ptie. 2. p. 752.

if

if they are compared with the description it gives of them. The colour of the head and trunk of the female varies, in some it is black, in others violet, the wings are sometimes transparent with a brown cloud at their tips, and sometimes they are brown, clouded with white; in his specimens, these were, as he informs us afterwards, "transparentes et sans couleur," but as he extracted them, before their time, from the cocoons in which they were inclosed, they were probably not come to their proper colour. My opinion, derived from this illustrious author, of the identity of *A. cærulescens* and *A. ænea*, is still further confirmed by this circumstance, that the former is always a female, and the latter, as invariably, a male insect.

Linneus to his *A. cærulescens* applies the term "fusca," which will not agree with our specimens, nor indeed with that preserved in the Linnean cabinet, but in his description in the *Fauna Suecica*, he says, "Corpus totum *airum*, cærulescens, immaculatum."

Many authors have looked upon Geoffroy's *Apis tota viridi-cuprea* (r) as synonymous with the male of our insect, but his description appears to me at variance with it, for he says of his "Elle est médiocrement velue. Les poils du bord des anneaux du ventre sont blancs." Whereas *A. ænea* is very

(r) Hist. Ins. Par. 2. p. 415. n. 15. *Apis cuprea*. Fourcroy. Ent. Par. n. 15.

hairy,

hairy, and the fringe of the segments of the abdomen is rufo-fulvous, and not white.

De Geer informs us that the larvæ of this Apis are exposed to the attacks of more than one *Ichneumon* (s). Panzer has figured both sexes very accurately.

DESCR. Acul.

CORPUS fusco-nigrum, punctulatissimum, rufo-villosum.

CAPUT magnum. *Maxillæ* validæ, prominentes, supra tomentoso-fulvescentes, apice tridentatae, dente exteriori acuto. *Antennæ* vix capitidis longitudine, tenues, subfiliformes.

(s) Tom. 2. ptie. 2. p. 753, 887, 888. Amongst others to *Ichneumon Apum*. *Vill. Ent. Eur.* 3. n. 249.

TRUNCUS

TRUNCUS supra rufo-subhirsutus, subtus pubes pallidiori. *Squamulae* ferrugineæ. *Alæ* fuscantes, albido subnebulosæ, nervis nigricantibus. *Pedes* rufescente-hirti, scopolis ferrugineis. *Tibiarum Spinulae* testaceæ.

ABDOMEN subglobosum, pubes ferrugineâ, nisi a latere vix conspicuâ, molle; segmentis margine viloso-pallidioribus. *Venter* lanâ densâ, ferrugineâ vestitus.

Maris *Corpus* subtus viloso-pallidum, supra ferrugineo-hirsutum. *Maxillæ* forcipatae, supra glabræ, apice bidentatae dente exteriori prælongo, interiori obsoletiusculo, truncato. *Facies* ante antennas vellere denso cinerascenti tecta. *Antennæ* thorace breviores. *Alæ* hyalinæ, apice obscuriores. *Pedes* pallido-hirti. *Spinulae* nigræ. *Abdomen* obscurè nigroæneum, per fascias hirsutum. *Anus* incurvus, emarginatus. *Venter* apice bidentatus.

Obs. *In maribus segmentorum abdominalium fibræ marginalis* haud albescit.

This insect answers the description which Fabricius has given of his *A. Tunensis* so well, that I think there can be little doubt of its being synonymous with it. I am not so certain that it is the *A. aurulenta* of Panzer, as his figure and description, although they come very near, do not quite coincide with my specimens of it. I do not know that it has been taken in England by any one besides Dr. Goodenough and myself.

apice

apice paulò obscuriores; nervis, strigâque marginali prope apicem, nigris. *Pedes* rufescente-hirti. *Femora* barbâ densâ cinerascenti. *Plantæ* posticæ dilatatæ. *Scopulæ* fulvo-aureæ. *Digiti* articulo extimo ferrugineo. *Spinulæ* testaceæ.

ABDOMEN ex oblongo subglobosum, nigro-aeneum, hirsutie densa rufâ vestitum. *Venter* lanâ fulvo-aureâ tectus.

Obs. *In adultioribus trunci et abdominis tergi hirsuties cinerascit, et ventris pallidior.*

Var. β frontis cornibus rectis, acutis (x).

Maris Corpus hirsuto-albicans. *Caput* cinereo-villosum, inerme. *Facies* anticè et inter antennas barbâ densâ albicanti. *Verticis pili* atri. *Maxillæ* apice bidentatae (y). *Antennæ* filiformes, trunci ferè longitudine. *Trunci* hirsuties longissima, anticè rarior. *Squamulæ* piceæ. *Abdomen* per fascias rufo-hirsutum. *Anus* subinflexus, integer (z). *Venter* glabriuscus.

Var. β dimidio minor.

It is observed by Linneus, under *A. licornis*, that Forskæhl saw that insect and *A. rufa* "copulâ connexas;" and whoever compares them both together will find that they differ only in such circumstances as are usually distinctions of sex,

(x) Tab. IO. **. c. 2. ♂. fig. 8. (y) Ibid. fig. 10.

(z) Ibid. fig. 20.

and

and that the former is constantly furnished with an aculeus, while the latter has no such instrument, but only the male organs: these reasons have induced me to consider them as different sexes of the same species.

Panzer's *A. fronticornis* is evidently nothing more than the aculeate of our *A. bicornis*, which agrees with the authentic specimen in the Linnean cabinet. His description appears to have been drawn from an insect that had been long disclosed, for in such the hair that covers the upper side of the abdomen fades to cinereous, and that upon the venter becomes paler than in more recent specimens. Linneus has described the abdomen by the term "rufum," which, in fact, belongs only to the hirsuties that covers it, as the abdomen itself is nigro-æneous in both sexes; this circumstance probably might lead Panzer, whose specimen, as I have just observed, was probably an old one, to look upon his insect as distinct from *A. bicornis*. The figure which Christius has given of the aculeate is far from a good representation of it, and his fig. 10. which he calls the other sex, appears to be a distinct species; it is certainly not *A. rufa*. That which he afterwards figures for *A. rufa* is a very different insect (a): his *A. pusilla* (b) comes very near to it, and I should refer to it as such if the antennæ were not so short in

(a) Vid. supra, p. 47.
12. fig. 14.

(b) Hymenopt. p. 161. tab.

his

his figure; whereas, in *A. rufa* they are strikingly long. Förster, in his catalogue of English Insects, has made two species out of the male; our α he calls *A. vernalis*, under which name he sent it to Linneus, and it is still in the cabinet. That illustrious naturalist very properly considered it as merely a variety of his *A. rufa*, as appears from a M.S. observation in his interleaved copy of the *Systema Naturæ*, which Dr. Smith very kindly allowed me to consult. Indeed it differs from β , which I take to be the common *A. rufa*, in nothing but size, being more than twice as big. Villars seems also to have fallen into the same error, as his *A. frontalis* exactly resembles our larger insect; his *A. rufa* is probably intended for our β : he has placed the former amongst his *Bombinatrices*; but where hirsuties is taken for the only diagnostic of that family, this is no proof of its being another insect, since *A. rufa* is as hairy as many genuine *Bombinatrices*. That which Scopoli (c), and after him Schrank (d), have given for *A. rufa*, appears to be a different insect; for the terms by which they define theirs, viz. "nigra; thorace abdominisque apice rufo," will scarcely agree with the true one; I have therefore made no reference to them. I think there is little doubt that Reaumur intended this insect by his "Mouche maçonnerie dont la maçonnerie n'est que de pure terre (e);"

(c) Ent. Carniol: n. 816. (d) Enum. Ins. Austr. n. 803:

(e) Tom. 6. Mem. 3. p. 92.

of which he says, "J'hésite presque à donner le nom d'antennes à deux cornes qui s'élèvent en devant de sa tête, car elles ne sont pas flexibles (*f*) :" words which clearly allude to the remarkable horns which the female carries upon its forehead. It is rather singular that no Entomologist should have before discovered this insect to be synonymous with *A. bicornis*. This great naturalist is the only author that has given any account of the mode of nidification of this species (*g*). It is not easy to ascertain what is the use of the horns with which the head of the females is armed, but it is probable that they assist her in the construction of her cells. Rossi has described another species distinguished by the same peculiarity (*h*), of which Panzer has given a figure (*i*). I am not sure that my variety β may not be a distinct species; but as it differs in nothing from α but the shape of the horns, I have not ventured to separate them. The larger males (*A. vernalis*, Forster) appear early in the spring; one of these, upon a very windy day in March, once amused me much by flying round me for some time, and at length alighting upon me. Upon variety β I found, in great numbers, a very small *Acarus*, the same which Reaumur informs us he took upon *A. violacea*. It was a hexapod with two long hairs in its tail, which seem-

Obs. *In adultioribus abdominis hirsuties rufa.*

A. bicolor, on account of its hairiness, is placed amongst the *Bombinatrices* by Schrank, Villars, and Geoffroy; but its inflected lip, and the hairy brush which covers the underside of its abdomen, prove that it belongs to the present family. Panzer's figure is not quite so accurate as his usually are, for the base of the dorsal segments of the abdomen, of this insect, is covered with ferruginous hair as well as the margin, although that which fringes the margin is the thickest.

 bicanti. *Antennæ* corporis ferè longitudine.

Truncus

Truncus supra fulvo-pubescentis. Pedes minùs hirsuti. Tibiae anticæ tomento nullo. Scapulae pallidiores. Abdomen magis angustum, lateribus albido-villosis, segmentis duobus anticis fulvo-pubescentibus, reliquis nigro, sed vix conspicuè, pilosis. Segmentum ante penultimum pallido-ciliatum. Ani fulvescit fimbria. Venter planiusculus, villosulus.

Var. ♀ abdomen subrotundo.

Obs. Inserendum abdominis segmenti antepenultiimi fimbria nigricat. In adultioribus thoracis et abdominis pubes fulva cinerascit.

I do not claim the sole merit of discovering the other sex of this species, and that the long antennæ, which form the distinction of the *Eucera* of Scopoli and Fabricius, are merely the character of the males; for Miller, in Mr. Gray's interleaved copy of the *Systema Naturæ*, before quoted, has described the female of *A. longicornis* in the following terms: "Fæmina antennis thorace brevioribus, abdomine latiore segmentis tribus ultimis margine et lateribus pilosis, albicantibus." M. Latreille, also, appears to have made the same observation; for in a letter to Mr. Mac Leay, dated April 26, 1801, he says, "Demandez un peu à votre ami s'il a trouvé la femelle de l'*Eucera longicornis*: car toutes ces abeilles à longues antennes ne sont que des mâles." The female has been described both by Schrank and Panzer; the latter has given a very accurate figure of it, under the name of *Andrena strigosa*.

strigosa. Variety β , at first sight, looks like a distinct species, but the difference in the shape of the abdomen, seems to arise from the accidental circumstance of the anal segments being more drawn in than in α , so that the base, of each of the three last, is quite covered by the apex of that which precedes it: whereas, in α the whole segment is exerted.

TRUNCUS

TRUNCUS supra hirsuto-cinereus. *Squamulæ piceæ. Alæ hyalinæ, nervis ferrugineis. Pedes pilis albicantibus hirti. Spinulæ flavæ. Scopulæ fulvescentes. Digitæ articulis extimus testaceis.*

ABDOMEN subglobosum, nigrum, basi cinereo, sed rariūs, villosum; segmento penultimo fimbriâ rufescenti. *Venter* villosulus.

This species resembles not a little the male of the preceding, variety β , but it is much smaller, the hirsuties of the body is cinereous, and the base of the abdomen is not so thickly covered with it. It has been mistaken, by many authors, for *A. tumulorum* of Linneus, but this, as we have shewn above (?), belongs to the genus *Melitta*, and exhibits no other mark of relation to the *Euceræ*, than its antennæ, which are longer than the thorax; a circumstance which it possesses in common with many other males of the family to which it belongs. Linneus having placed it next to *A. longicornis*, and employing terms in the definition of it, which imply that it is related to that insect, succeeding Entomologists took this for granted, and thus have erred universally concerning this *Apis*, not one author, that I have had an opportunity of consulting, being acquainted with the true *A. tumulorum*, and the majority of them mistaking the insect now before us for it. Yet had the definition which

(?) Vid. supr. p. 56, 57.

Linneus

Linneus has given of it been attended to, this mistake would have been avoided, for the terms "Pedibus, maxillisque flavescentibus" will not by any means agree with *A. lingua*. In the *Fauna Suecica* other characters are added to the above, which, if they had not been overlooked, would have furnished a further proof, that this insect was not the insect of Linneus. "Magnitudine dimidiæ *Muscæ domesticæ*; toto corpore nigra, exceptis pedibus et maxillis pallidè luteis. Antennæ filiformes, corporis ferè longitudine, subitus pallidiores." Fabricius finding that the definition of Linneus would not suit the insect which he mistook for *A. tumulorum*, has altered it, omitting "pedes flavi," the most striking distinction of the true one, and adding hirsuties, a circumstance which does not belong to it (m). I am not, at present, acquainted with his *Eucera tumulorum*.

(m) Antennis longitudine corporis hirsuti nigrique, mandibulis flavis.

TRUNCUS.

TRUNCUS. Thorax pube flavescens mollis. *Squamulae* fulvæ. *Alæ* subhyalinæ; nervis, excepto costali fusco, ferrugineis. *Pedes* nigri, albido undique pilosissimi, postici potissimum.

ABDOMEN fuscum, basi albido-pubescent, squamulis / pilis brevissimis pallidis, anum versus præcipue, incanum. *Venter* segmentis margine pilis pallidè aureis ciliatis.

This insect is somewhat similar to the aculate of *A. longicornis*, but it is much larger, and its abdomen is nearly covered with minute scales. Part of the thorax of the specimen in Sir J. Banks's cabinet, has evidently had the hair rubbed off; this defect is attempted to be remedied in the figure I have given of it. I have never seen this insect in any other cabinet; its male, I have very little doubt, is one of the *Euceræ*, or long horned bees.

62. *A. nigra*, hirsuto cinerascens; antennis subtus *Druriella*.

Var. β ore facieque anticè ex flavo rufescentibus, pedibus nigris.

Panzer's

Panzer's figure of this insect is extremely accurate, except that the tibiæ and tarsi are more yellow than in any specimens I have met with; the posterior tibiæ, from the pollen, of which they usually retain some quantity, appear yellower than the others, but this not the real hue of the hairs, which are pale with little or no tinge of that colour. The eyes, in his specimen, when the insect was living, he informs us were of a fine green, "læte virides," in those that I took they were blue-grey. The bifid mucro, which he mentions as terminating the anus, is merely a little tuft of rigid hairs which guard, on each side, the minute segment that terminates the abdomen; under a common lens these have exactly the appearance he describes. What he calls spots of the front, are rather lobes, for they are not entirely, but only in part, insulated from the blackness of the posterior part of the face, by the intervention of the yellow, which is the colour of the anterior.

Venter posticè depresso-concavus tomentoso-fulvescens.

Var. β corporis hirsutie grisea; antennis scapo immaculato.

As the sexes of *A. furcata* are so unlike each other, that no common character would include them both, I have, therefore, been under the necessity, as in some former instances, of making a separate one for each. I do not give these individuals as male and female upon my own authority, but Mr. James Trimmer, upon whose accuracy I can rely, has taken both out of the same nest. Upon their mode of nidification I have enlarged before (p). Panzer's figure and description, which belong to the male, vary a little from our specimens, but I think there can be no doubt of his intending the same insect.

Var. ♂ corpore cinereo-villoso; trunco supra pube flavescenti; abdomine segmentis margine tomentoso-albis.

When my *Synopsis Specierum* went to the press; I had seen only variety ♂ of the male of this insect; but since that, in July last, I took recent specimens of both sexes frequenting the flowers of *Erica*, in a sunny sand-pit near Combe Wood, a spot well known to the Entomologists of the Metropolis, and producing many very rare insects: As all that I was then able to examine agreed together;

gether, I thought it most adviseable to correct my *Nomen Specificum* and description by them: the specimen from which I originally described being, probably, one that had been disclosed so long from the pupa, as to change the colour of its hirsuties. Panzer's figure, which evidently belongs to the male of our insect, was taken from one in the same predicament; and if I am right in my reference to Fabricius, concerning which, however, I have my doubts, his description was drawn from one of this sort too. Geoffroy for his, "Abeille à levre jaune et anneaux du ventre blanchâtres," which appears synonymous with this variety, refers to one described in the first edition of the *Fauna Suecica*, but which afterwards seems to have been omitted by Linneus. This, however, although it belongs, I think, to the present family, I suspect to be a different species, perhaps *A. bimaculata*; for Linneus says of it: "Abdomen nigrum segmentis villosis canis 5 vel 6," which implies that not the margins only, but the whole of these segments was covered with hoary hairs. Geoffroy says of this *Apis*: "Cette espèce forme dans la terre des trous horizontaux qui sont fort longs et divisés au bout en plusieurs cellules. On voit ces trous dans les terreins coupés perpendiculairement en forme de murs (q)." From an inspection of the female, of which I had seen no specimen, when I made the arrangement adopted in my synopsis, I find that *A. rotundata*

(q) Tom. 2. p. 413, 414.

ought

ought to follow *A. bimaculata*, which it resembles in many respects.

A. PALLICINCTA. 67.

Since the printing of my synopsis, I have again seen the insect which I had described under this name, and find it to be *M. fodiens* before noticed (*r*). I drew my description of it long ago, before I was acquainted with the characters which distinguish my first family of *Melitta*, from a specimen, the only one I had then seen, in Mr. Drury's cabinet (*s*), the structure of whose proboscis I could not ascertain. As it seemed to have a general resemblance to some of the individuals of this family, particularly *A. rotundata*, I placed it next to that insect; although I observed even then that it wanted one of the most prominent characters of the subdivision, the *os crassum*. A year or two after this I took it myself, and finding its instrumenta cibaria to be those of a *Melitta* possessing peculiar characters, I did not recollect that it was the same insect I had described before as an *Apis*.

From an inspection of the authentic specimen preserved in the Linnean cabinet, I do not hesitate to give the aculeate of the present *Apis* as the genuine *A. retusa* of Linneus. That specimen is, indeed, smaller than our English ones usually are, not quite so hairy, nor is its hair of so deep a black; but these circumstances appear to be entirely accidental: insects of different climates, and sometimes those of the same, vary much in size; and the hair of an *Apis* newly disclosed from the pupa, as to colour and density, is often very different from that of the same individual when it has been long exposed to wind and weather. In other respects the Linnean specimen is the very counterpart of ours, and agrees exactly with the description in the *Fauna Suecica*. " *Magnitudine A. mel-
lificæ. Corpus totum nigrum pubescens. Tibiæ
posticæ dilatatae, extus vellere brevi, denso, flavo.*"

(y) Schrank. *Enum. Ins. Austr.* p. 399.

This

This insect, however, has been mistaken by Fabricius and many other Entomologists, and confounded with another. As it is usually very hairy, this author regarded it as a *Bombinatrix*, and took it for granted that it could be no other than the *A. acervorum*, Linn. Possessed with this idea, he added to "hirsuta, atra," the Linnean definition, the terms "tibiis posticis ferrugineis," in which he has been followed by Gmelin and others. But had he paid due attention to the description of the Fauna Suecica, he would have been convinced that, by *A. acervorum*, Linneus intended a very different insect. "Præcedenti (z) similis," says he, "sed minor: toto corpore nigro, immaculato exceptis setulis quibusdam circa collum sulphureis." These terms plainly exclude the tibiæ ferrugineæ of *A. retusa*, of which I never saw a specimen, and I have seen many, that had any sulphureous hairs about its neck. I suspect that the specimen preserved in the Linnean cabinet, as *A. acervorum*, is not the original one, although its label is an autograph of Linneus. When an insect with such a label answers to the description of Linneus, no doubt can remain of its authenticity; but when it varies from it, its claim to be considered as the original specimen is a good deal invalidated. In the present instance, the specimen differs from the description in several respects; its wings are violet, it has no sulphureous hairs about its neck, and

(z) *Nempe A. lucorum*, Linn.

the

the disk of the scopa, or brush, which covers the underside of its abdomen, is tawny; it belongs to the same family with the *Abeille maçonner* of Reaumur (*a*), and I strongly suspect it to be the female of that very insect, which that author describes in terms which agree well with it. "Les uns doivent devenir des abeilles très-noires, aussi noires, mais plus veluës que les perce-bois; elles ont seulement un peu de jaunâtre en-dessous à leur partie postérieure (*b*)."
I shall give a fuller description of it in the margin (*c*), Concluding that *A. retusa* was *A. acervorum*, and unacquainted with any insect that would agree with the Linnean character of the latter, Fabricius has excluded it from his last work, *Entomologia Systematica Emendata et Aucta*, as a nonentity; expressing only a suspicion that it may possibly be his *Andrena pilipes* (*d*). With respect to other synonyms of the aculeate, the insect Christius has figured for *A. retusa* (*e*)

(*a*) Tom. 6. tab. 7. fig. 1, 2, 3. It belongs to the fourth subdivision, of the second section, of my family *lalio inflexo*. (**. c. 2. δ).

(*b*) Reaum. ubi supr. Mem. 3. p. 60.

(*c*) DESCRIPT. Acul. *Corpus atrum, hirsutum. Maxillæ validæ, dilatatæ, apice extus bidentatæ, dente exteriori acuto. Alæ corpore longiores atro-violascentes. Pedes atri, tarsis rufis. Abdomen subglobosum, atrum, undique hirsutum, ventris scopâ disco fulvo.*

(*d*) *Melitta pilipes* of this work, vid. supr. p. 97, 98.

(*e*) Hymenopt. p. 119. tab. 9. fig. 4.

appears

appears to be a *Bombinatrix*, and I think represents one that I shall hereafter describe; his *A. rufipes* is the true *A. retusa*. Under the same name Miller, in the MSS. so often quoted by me, has noticed our *Apis*; to his definition, inserted amongst the synonyms, he adds this short description. "Tibiae tarsi postici rufo vellere extus hirsuti." Ray appears to have described this bee twice, but as this may seem too bold an assertion to hazard with respect to a writer of his acknowledged accuracy, I shall assign my reasons at large for being of that opinion. The description he gives of his *Bombylius*, n. 4. so exactly suits our insect, that I think no one will deny them to be synonymous; the doubt will be attached to the other which I have quoted, viz. his *A. sylvestris muraria nigra*. His description of this, "Tota nigra est, corpore breviusculo, cruribus duntaxat postremis obscuro aurantii colore rubentibus," will suit our insect very well; but it is not so much upon this that I ground my opinion, as the following circumstance. This illustrious author informs us, that it makes its nest in walls and banks, and that it abounds at Kilby, near Hill Morton, in Northamptonshire(f). Now, in the beginning of July, 1797, in company with Mr. Marsham, at Wandsford and Ufford, in the northern part of the same county, I discovered *A. retusa* in the greatest abundance, frequenting the walls made of the

(f) Hist. Ins. p. 243.

stone

stone of that country (g): a strong proof, as his description agrees with ours, that we both mean the same insect. It is probable, that, in his travels, seeing this bee so plentiful about the walls, at the place above-mentioned, he took it for a different species from the one he had seen less frequent in other parts, and in a different situation. As some doubts, however, must still remain, without I could visit the very spot, where he found it, I have placed a query after this synonym.

The male of this *Apis* is so totally unlike the female, that it has been regarded by all authors, not excepting even Linneus himself, as a distinct species. In an interleaved edition of the *Systema Naturæ*, containing MS. notes of that great Naturalist, and now in the possession of the President of the Linnean Society, (who, with his accustomed liberality, has permitted me to copy such of them as relate to the present genus), I find it described under the name of *A. pennipes*, and placed next to *Melitta cunicularia*: upon the authority of Forster, it is said to be a native of North America: it is inserted, under the same name, in Forster's Catalogue of British Insects, published in 1770. Professor Pallas and Schrank, denominate it *A. plumipes*. Fabricius, and after him Panzer, call variety α , *A. Hispanica* (h); and variety β , *A. pi-*
ipes.

(g) Kettering stone.

(h) I am not quite certain that the *A. Hispanica* of Fabricius is synonymous with this; his description agrees: but ours in size

lipes. When the insect first makes its appearance in the spring, the down of the upper side of the body, the anus excepted, is of a reddish yellow, answering to the description and figure of the former; later in the year, when it has been long disclosed, this becomes cinereous, or greyish, and then it agrees with those of the latter. I suspect *A. cochlearipes* of Christius to be a different species, for there are several that are distinguished by similar pedes secundarii, although Panzer has referred to it as synonymous with *A. pilipes*. It is singular that an insect should be described under so many different names, and prove at last to be entitled to none of them. This point I shall now endeavour to prove as briefly as possible. When I first set out in my entomological career, I began to notice the motions of this *Apis*, and have continued to do so occasionally ever since. Early in the spring the male may generally be seen attendant upon his swarthy bride, fluttering round her, or hovering over her, while she, with great coolness, collects the honey from flower to flower, without bestowing any attention upon him: if she departs, he departs; and if she returns, he returns likewise. During the season of courtship, his whole employ-

size is greatly smaller than *A. virginica*. Panzer's certainly belongs to ours. Linneus, in the MS. notes mentioned above, has described another *Apis* under this name, which he received from Forster, in these terms: *Hispanica A. nigra, abdomine testacco apice nigro, segmentis duobus penultimis albis.*

ment

ment seems to be to attend upon her; but whilst the halcyon days of love are over, like many other husbands, he goes about his business, and leaves her to take her flights in solitude. I was often entertained with this scene, before I was aware of any connection between these little creatures; but at length I could not help suspecting, in spite of the total want of resemblance between them, that they were different sexes of the same species: to ascertain this point, I examined anatomically a number of each; and found that the black ones were always aculeates, and the others as constantly males. I found both afterwards in the same nest, which has likewise been done, more than once, by my friends the Rev. Peter Lathbury, and Mr. James Trimmer. These circumstances furnish as strong presumptive evidence, in support of the fact I assert, short of seeing the sexes copulâ connexos, as can be desired. Ray, indeed, makes an observation with respect to the male, which seems, at first sight, to militate very strongly against the opinion here advanced: after describing it in terms which leave no doubt as to its being the same insect, he says: "In muris et aggeribus terrenis nido pro fætu constituit prioris nido (viz. *A. sylvestris muraria nigra*) similem, in quem substantiam quandam dulcem melle crassiotrem ei nutriendo recondit (i)." This, however, is easily accounted for; he would certainly never dream of any connection

(i) P. 243.

between

between two insects so entirely unlike each other, without he had noticed some circumstances that might excite such suspicion; and therefore, of course, if he observed the male go into a nest, he would immediately conclude that it was peculiar to it, and so, vice versa, with respect to the female. What he says with regard to the two nests being similar to each other in form, and built in the same situation, is a further proof of this.

ABDOMEN atrum, pubescens, basi hirsuto-fulvum.
In honorem D. Haworth, Generis Narcissus Monographi, Entomologiae etiam studiosi, hanc Apem nominavi.

This species, at first sight, strongly resembles the male of the preceding; but upon a close inspection, we find that its intermediate legs, instead of being longer, are shorter than the posterior; their plantæ, also, have only a dense beard of black hairs on one side, without any of those very long ones, along the whole of the tarsus on the other, which form a remarkable character of the male sex of that insect. Its maxillæ, likewise, have no yellow spot; and the anterior part of the nose alone is pale yellow, and not the whole face below the antennæ. The specimen from which I drew my description, is in the Museum of Mr. Haworth; I have since seen it amongst the English insects of Major Gen. Davies at Blackheath. I have by me two or three other exotic males, whose intermediate legs resemble those of *A. retusa* and *A. Haworthana*, in being, what Fabricius terms, fasciculato-pilosí.

This

APIS. (**. d. 2. α. β.)

This little insect varies somewhat from the characters of the present family, for the valvulae, instead of being strait, are incurved; and the interior laciniae are not pointed at their tips; in general habit, also, it is unlike the rest of the individuals that compose this section. It is, however, more nearly related to this, than any other family; for it exhibits the following characters, which combined are peculiar to it: its exterior palpi, namely, consist of six articulations, and its interior of two; not to mention that the nose and lip, of the male, are of a different colour from those of the other sex, a circumstance which usually distinguishes the insects of this section. *A. cyanea* approaches so near to *A. cærulea* of Villers, that I strongly suspect it to be merely a variety of that insect; in that case it ought to be denominated by the name he has given it.

DESCR. Acul.

CORPUS violaceum, supra glabrum.

CAPUT

CAPUT punctatum; atro-pilosum. *Genæ* barbatæ. *Antennæ* capitis ferè longitudine, nigrae, subtus pallidæ.

TRUNCUS. *Thorax* glaber, nitidissimus, iricolor, linea longitudinali intermediâ impressus, punctatus disco lævissimo. *Metathorax* et *Pectus* atro-pubescentia. *Squamulæ* violaceæ. *Alæ* fusco-nigræ. *Pedes* violacei, atro-hirti. *Plantæ* atræ, undique hirsutissimæ. *Digiti* picei. **ABDOMEN** subiricolor, latum, supra glabrum, punctulatum. *Anus* fimbriâ atrâ. *Venter* anum versus atro-hirtus.

This most beautiful insect is in Dr. Latham's cabinet, amongst his English *Apes*, but he does not recollect where it was taken, or upon what authority he considers it as English(o). It has been received from Jamaica by Mr. Drury, who has given an excellent figure of it, of which I was not aware when I caused it to be engraved for this work. I have also received it from Mr. Marsham. Its place ought to be next to *A. violacea*, Linn. which it a good deal resembles, except that, instead of black, its body is violet; and, on the contrary, the wings, instead of violet, are black. The prismatic hues upon the thorax are very brilliant; upon the abdomen they are much fainter. Since I wrote the natural character of this section, I find that the interior laciniæ, of the insects that belong to it, are lineari-lanceolate, and shorter than the exterior.

DESCR. Acul.

CORPUS hirsutie pallidè flavâ.

CAPUT. Os ferrugineo-barbatum. *Proboscis* trunci longitudine, palpis exterioribus acutis.

TRUNCUS. Thorax hirsutie rufo-fulva, s. aurantiacâ, tectus. *Squamulae* rufo-piceæ. Alæ subcoloratae, apice nervisque nigris. Pedes nigri, hirti. Femora dense flavidò-barbata. *Corbicula* flavescens. *Scopulae* ferrugineæ. *Spinulae* castaneæ. Digitæ picei.

ABDOMEN triangulare, supra hirsuto-fulvo-flavum.

Var. β minor; thoracis hirsutie dilutiori; alis coloratis, apice immaculatis; abdomine brevi, subgloboso. An eadem?

γ præcedenti similis, sed minor; abdomine triangulari.

♂ thoracis hirsutie fuscâ, qui color ex pilis nigris fulvisque mixtis exoritur; magnitudine præcedentem æquiparat.

ε præcedentibus dimidio minor.

Maris *Maxillae* supra pallidæ, barbâ nigricanti.

Antennæ thoracis ferè longitudine, articulis subarcuatis. *Scopulae* fusco-nigræ. *Abdomen* angustius, ani extremitate nigro-villosâ.

Var. β tertia parte minor; spinulis atris; scopolis pallidioribus, vix auratis.

γ adultior, corpore toto hirsuto-cinerascenti.

Obs. In hac varietate thorax paululum flavescit.

Of

Of these varieties I take α to be the female; γ and δ to be the neuters of the largest size(y); and ϵ the small neuter; β I suspect may be a distinct species, in size it is intermediate between α and γ . Variety β , of the male, is considerably less than α , but it differs from it very slightly in other respects; it may be the male of variety β of the other sex, but both are too similar to the rest to be separated, without a nest could be found, which contained them alone. Variety γ , of the male, is *A. senilis* of Fabricius, as appears by the specimen in Sir J. Banks's cabinet, which he labelled. The cinereous hue of its hirsuties is merely occasioned by age; the thorax, even in this, retains a tinge, very faint indeed, of its original colour.

ABDOMEN subglobosum, supra hirsuto-fulvum, basi penicillo pilorum cinerascentium utrinque ornatum.

Var. ♂ minor; scopolis vix auratis; abdomine fasciâ obscurâ nigricanti.

D. Francillon, *cujus museum ditissimum stupendos insectorum thesauros, item quamplurimorum delineationes accuratissimas exhibet, hoc insectum nomine insignitur.*

This insect would by many be placed aside as a variety merely of the preceding, which indeed, at first sight, it resembles much; a close inspection will, however, convince the skilful entomologist that it is distinct. The hair of its head, except what grows round the base of the antennæ, is black, as is also the corbicula of the posterior tibia; the abdomen is of a different form, and its hair is of the same colour with that of the thorax, not to mention slighter differences; besides, which I think is a strong argument, its smallest neuter is less than that of *A. muscorum*; so that were this admitted to belong to that species, it would have neuters of three different magnitudes.

Obs. *In utriusque sexus adultioribus thoracis et ani hirsuties cinerascit.*

Memoriæ D. Beckwith Angli, Entomologi peri-
tissimi, hoc insectum consecratur.

This insect very much resembles *A. floralis*, but instead of four narrow ones, the abdomen is distinguished by one broad black band only; as each of these has, likewise, a male agreeing with it, I think I am justified in considering them as distinct species. Variety β of this sex is not half the size of α . I have observed not seldom a variation in the size of individuals of this sex, which leads me to suspect that, in each nest, there may be two descriptions of males as well as of neuters.

Curtis-ella. 79. *A. hirsuto-pallida;* thorace fulvo; abdomine atro, basi rufescenti.

Obs. *In hac saltem varietate, si non in reliquis, in adultioribus, corporis toti hirsuties fit cinea-rea, etiam ani; trunci disco, abdominisque fas-ciâ mediâ, hirsutis, atris. In omnibus apophy-ses secundariæ articulo secundo subtus, vel po-tius antrorum, tomentoso-ferrugineo, sed hoc tomentum sub hirsutie longiori pallidâ plerum-que delitescit.*

Maris *Maxillæ* barbâ rufescenti. *Antennæ* tho-racis ferè longitudine, articulis subarcuatis. *Spinulæ* nigræ. *Scopulæ* dilutiores. *Abdomen* segmento secundo quartoque fasciâ atrâ.

Var. β abdomine fasciâ atrâ unicâ.

The insect I have just described is the genuine *A. sylvarum* of Linneus, as appears from the authentic specimen, but it is not the *A. sylvarum* of Schrank and Rossi, which we shall shortly notice; *A. Scylla* of Christius seems intended for it, al-though his figure, if so, is very inaccurately col-loured. It is rather doubtful whether this be the insect

insect Ray meant by his *Bombylius*, n. 9, although I think that most probably it is; his description is too short to enable me to determine with certainty. Linneus has expressed the colour of the anus of this bee by the term *ruber*, and Fabricius by *rufus*, but it really exhibits alternate fasciæ of rufous and pallid, a mixture of colours which Linneus, upon some occasions, denominates *griseus*(z). The reader will observe that β , γ , and ϵ , varieties of the neuter, differ from each other in size, which will give three dimensions of that sex; may not δ and ϵ , which, except in that respect, are exactly similar, belong to a distinct species?

83. A. supra hirsuto-flava; thoracis fasciâ atrâ. *fragrans.*

Apis fragrans hirsuta flava, thorace fasciâ nigra.

Pallas. It. 1. p. 474. n. 75.

flavescentium ante antennas signat. Occiput hirsutie flavâ. Antennæ thoracis longitudine, articulis subarcuatis.

TRUNCUS. *Thorax fasciâ hirsutâ inter alas atrâ.*

Pleuræ flavo-hirsutæ. Squamulæ nigræ. Alæ subhyalinæ, apice paulò obscuriores, nervis ferrugineis, crassioribus nigris. Pedes atri, hirti. Femora hirsuto-cinerea. Spinulæ castaneæ. Scopulæ ferrugineæ. Digitæ rufi.

ABDOMEN oblongum, hirsutie densâ viridi-flavâ vestitum.

This insect is beyond a doubt *A. fragrans* of Professor Pallas, which Fabricius, for what reason I cannot conjecture, has called *A. pratorum*, giving the name of *A. arbustorum* to that which he mistook for the Linnean *A. pratorum*. Pallas says, "fæminæ odore roseo flagrantissimæ." I have never met with a female or neuter; but the male, which with us is now and then to be met with in the autumn, has the same agreeable scent.

Latreill- 84. *A. supra hirsuto-flava; thorace inter alas, ab-ella.* domineque fasciis duabus, atris.

ABDOMEN triangulare, supra hirsuto-flavescens, segmento secundo tertioque fasciâ atrâ.

In honorem D. Latreille Galli, in entomologiâ doctissimi, operis ingeniosissimi, quod characteres insectorum novos tradit, auctoris.

A. Latreillella is not unlike the preceding insect, and has the same remarkable scent of roses; but it is also a male, is smaller, its abdomen is of a different form, and is distinguished by two narrow black bands, which are scarcely separated by a few pale yellow hairs; these circumstances furnish a sufficient warrant for my considering it as distinct.

A. maura of Christius comes very near to this, if it be not altogether the same.

85. *A. supra hirsuto-flava;* thorace inter alas, ab-*Rossicella*. dominisque fasciâ, atris.

Age,

Age, as I have before observed, makes a great alteration in the colour of the hirsuties of the *Bom-binatrices*. The bright and beautiful yellow, which adorns the insect before us when recently disclosed, fades, in such as are old, to a pale, dirty yellow. From a specimen in this state, Schrank probably drew his description, for I have no doubt of this being his *A. sylvarum*. A specimen of this insect in my cabinet, has one leg covered with cinereous hairs, while those of the other five are black.

86. *A. atra*, hirsuta; thorace anticè, scutello, ano-*Leeana*-que, flavis.

In honorem Rev. D. Francis Jungermanniarum Angliæ futuri elucidatoris, qui et in Entomologia multum necfrustra sudavit.

The whole hirsuties of this bee is black, except a subinterrupted yellowish band at the tail. I suspect

pect one of the three species that I have described last, to be the male of that which I am next to notice, but as I know not which to fix upon, I must leave that point undecided till I can meet with the nidus. These three exactly resemble each other in form and habit, differing only in the colour of their hirsuties, whence a suspicion arises in my mind, that after all they may turn out to be varieties only of the same species.

Plantæ

Plantæ posteriores absque auriculâ. Scopulæ ferrugineæ, subauratæ. Digitæ rufo-picei.

ABDOMEN, in mortuo saltem, subglobosum, nitidum; segmentis tribus anticis atro-subhirsutis. *Anus* incurvus, flavo subinterrupte hirsutus, segmento ultimo glabro, inflexo, subacuminato.

This insect, although it does not entirely agree with Panzer's description, is most accurately represented by his figure of his *A. campestris*, so as to leave no doubt of their identity: if my figure of it had not been taken when I received the number which contains his, I should have omitted it as unnecessary. The aculeate of this bee, as well as of two or three others of the present section, has no corbicula, nor is the apex of its posterior tibiæ furnished with a pecten, or its plantæ with an auricle at their base, like the other *Bombinatrices*.

This is the true *A. lucorum* of Linneus, as appears upon a comparison of it with the authentic specimen

specimen in the cabinet. b, although at first sight it appears distinct, upon a close inspection will be found to be merely a variety of a. The former of these has been mistaken by Rossi for *A. Hypnorum*, Linn. (which is a very different insect (a), and approaches nearer to *A. Muscorum* and *Beckwithella*), it is extremely well figured by Panzer under the name of *A. cæspitum*. Of the latter, I have seen only the single specimen, except the Linnean, which I have in my own cabinet. The black band of the thorax, in the authentic specimen, is nearly obsolete.

Linneus, in his description of this insect, takes no notice of the yellow hairs which cover its scutellum. This circumstance induced Fabricius to consider another as *A. hortorum*, and to give this as a new species under the name of *A. ruderata*. It is, however, the genuine *A. hortorum*, as appears upon a comparison of it with the authentic specimen of the Linnean cabinet. The Fabrician *A. hortorum* stands by it, but without a label. The synonyms of Scopoli seem to belong to a variety of *A. terrestris*, for he describes it in these terms: "Thorace anticè flavo; abdomine fasciâ flavâ: apice albo (d)." To suit the insect before us, or

(d) Ent. Car. n. 817. Ann. Hist. Nat. 4. p. 10. n. 2.

that which has been mistaken for it, it ought to be “abdomine basi flavo.” Müller, in his *Zoologia Danica*, has described this *Apis* under the name of *A. paludosa*: of course his *A. hortorum* is another, most probably synonymous with that of Fabricius. The *A. hortorum* of Christius (e), as far as I can judge from his figure, is no *Bombinatrix*.

The head of this species is much longer, in proportion to its width, than is usual in this family, in shape it bears no faint resemblance to the head of a dog, while others, with very little stretch of the imagination, may, in this respect, be regarded as similar to the cat.

Ray seems at a loss to conceive what can be the use of the complex machinery of the proboscis; we, who know the admirable art and contrivance manifested in the construction of this organ, need not wonder, but we shall be inexcusable if we do not adore.

This insect exhibits the same peculiar characters as *A. campestris*. *A. autumnalis* of Fabricius, *A. saltuum* of Panzer, and *A. monacha* of Christius appear to me to be all intended for variety β of the male. This variety is common late in the year upon thistles, and is nothing more than α grown grey from age: its wings, when it is in this state, will always be found to be torn at their tips. The synonym of Ray, n. 15. I refer to the aculeate of this *Apis*, because he says, "Superior area lata est, et media parte in angulum excurrit ad frontem," which is exactly the case with ours. His description was probably taken from a specimen in which the hair was faded.

This is again another of those *Bombinatrices*, which, like *A. campestris* and *Barbutella*, have no instruments for carrying or preparing masses of pollen. The posterior tibiæ, of one specimen in my cabinet, is covered from one end to the other with a thin coat of pale earth, mixed with particles of sand; they probably use this in constructing their nests or cells. This species was known to Geoffroy, who has described it with great accuracy in the following terms: "Cette grande espèce est noire. Le haut ou la base de son corcelet a une bande de poils jaunes citrons. Les deux tiers supérieurs du ventre sont noirs, ensuite il y a quelques poils jaunes, et son extrémité est blanche. Les ailes sont brunes." He has neglected, however, to notice the black extremity of the anus.

que ornato, secundo citrino, tertio atro, ano
albido.

Var. β minor; abdome segmenti primi peni-
cillis nigris, segmento quarto etiam atro.

Maris

Maris *Maxillæ* pallidæ. *Antennæ* capite longiores, articulis rectiusculis. *Truncus* supra cingulo antico hirsuto, citrino. *Pleuræ* citrino-villosæ. *Tibiæ* posticæ supra vix pilosæ. *Scopulæ* ferrugineæ. *Abdomen* segmentis duobus anticis hirsutis citrinis, proximis duobus atris, ano albo.

Obs. *Feminam nondum vidi, mas neutro duplo major.*

This, I take to be the insect which Fabricius looked upon as *A. hortorum* of Linneus. The tuft of yellow hairs, which is observable on each side of the first dorsal segment of the abdomen, is sometimes black, which brings this species very near to *A. terrestris*. In that, however, the whole of this segment is hairy, and not the sides only; its abdomen is also proportionably longer, and the scopulæ are of a different colour; not to mention, that in one, the exterior palpi are acute, and in the other, truncate. I have not yet met with the female of this species, but Geoffroy knew it.

Var. ♂ thoracis basi, abdominisque fasciâ, fulvis; ano pallido.

Obs. *Hujus Apis palpi exteriores longiores quam vulgo obtinet in hac familiâ.*

I had followed my friend Mr. Marsham in considering variety γ as a distinct species, on account of its tawny anus, at the same time still suspecting from its great similarity in other respects to *A. terrestris*, that it might be merely a variety of that insect. Reaumur's observation upon this species, gave strength to this suspicion—"Ceux (les poils) de la troisième (bande) ou du bout du corps, sont blancs ou jaunâtres (h)," says he; and receiving information from Mr. James Trimmer, that he had found this in the same nest with α , I was convinced at last that my suspicion was well founded, and that it ought only to be considered as a sexual variety. I take it to be the female, from the circumstance of its making its appearance early in the spring. The synonym of Ray belongs to one that retains the faintest trace possible of the yellow band

(h) Reaum. tom. 6. Mem. 1. p. 34.

of

of the thorax, and which, indeed, is scarcely visible to the naked eye. I have a specimen of this in my cabinet: it furnishes an instance of the tendency of these insects to vary, even such as have been recently disclosed, (for of this description is my specimen), in the colour of their hirsuties. If the band vanishes from the thorax, it may vanish, likewise, for aught we know, from the abdomen; in that case, α would become *A. soroensis*, Fab. I mention this, to shew how very liable we are to err in our determination of species in this family. Ray has given the male and common aculeate as distinct species, misled by the different hue of the anterior part of the thorax, and of the abdominal band, which in the one is pale, and in the other tawny-yellow. These, however, in variety β of the male, are also of the latter colour, but α is the most common. I have often been amused, at the time of the sycamore's being in flower, with seeing these insects, by myriads, busily engaged upon its very summit, in collecting honey and pollen from its blossoms, and making a hum that might be heard at a considerable distance, and this even after sun set. They are as alert in the morning; I have frequently seen them at work in my garden, when the gooseberry was in blossom, before seven o'clock.

ABDOMEN

ABDOMEN ex ovato oblongum, hirsutum, segmentis duobus anticis flavescens, intermedio atro, ano ferrugineo.

In honorem D. T. G. Cullum, Baronetti, viri amicissimi, et Naturæ indagatoris docti, indefessi.

It is probable that in a recent specimen (that from which this description was drawn, having apparently been some time disclosed) the hirsuties of the body of this species would be of a lemon colour. It differs from the preceding in the form of its abdomen, and of the joints of its antennæ, and only one abdominal segment is black.

pratorum. 103, A. atra, hirsuta, ano fulvo; thorace anticè flavo.

Apis pratorum hirsuta nigra, thorace anticè flavo, ano rubro.

Digiti obscurè ferruginei.

ABDOMEN oblongum, hirsutum, atrum, ani extremitate fulvâ.

Var. β dimidio minor; scopolis fuscis.

γ præcedenti duplo minor; alis subcoloratis nervis ferrugineis; abdomine subgloboso.

Obs. *In plerisque rudimenta, obscurissima tamen, fasciæ anticæ flavescens abdomen exhibit.*

This is the genuine *A. pratorum* of the Linnean cabinet; *A. arbustorum* of Fabricius, which he gives as *A. pratorum*, is a different insect, as we shall see hereafter. I have a strong suspicion that the one before us is nothing more than a variety of *A. sub-interrupta*, before described, for a very faint trace of a yellow fascia is observable upon the abdomen of α and β , but not upon γ ; this last is the smallest *Bombinatrix* with which I am acquainted.

**104. A. atra, hirsuta, ano rufo; thoracis limbo, *Albinella*.
abdominisque lateribus, cinerascentibus.**

ABDOMEN ex globoso ovatum, hirsutum, segmento primo secundique margine utrinque cinerascentibus. *Anus* acutiusculus, rufo-fulvus.

Var. ♂ thorace atro basi obscurè flavescente; pedibus hirsutie sordidè nigricanti.

I had printed my *Synopsis Specierum* before I saw Panzer's figure of this insect, or I should have given it under the same name, I suspect it may be the male of one I shall shortly describe. Its abdomen is narrower at the base than is usual in this family. Variety ♂ may possibly be the male of a different species. Its trunk, instead of being surrounded with cinereous hairs, has only an obscure yellowish band next the head, and the base of the abdomen,

abdomen, except it be viewed *a latere*, appears black, with a cinereous spot on each side. In form, however, and habit it agrees with α .

105. A. hirsuta, fusco-cinerascens, ano fulvo ; tho-*Derhamella*.

The difference of size between β and γ , which I take to be the two descriptions of neuters, and α , which is the female, is so great, that were they not most exact counterparts of each other in every other respect, I should scarcely be able to persuade myself of their identity. *A. pratorum* of Christius, as far as I can judge from his figure, is nothing more than the largest of the two neuters of this species. The male has usually been considered as a distinct spscies: Fabricius mistook it for *A. pratorum*, Lin. but changed its name to *A. arbustorum*. That it is not *A. pratorum*, we have shewn above; it remains that we assign our reasons for giving it as the male of the species before us. In the first place Reaumur, speaking of the variations of

of colour observable in the cloathing of the *Bombylinæ*, has these words : “—dans le même nid j'ai vu naître des Bourdons de même taille, qui différoient entr'eux par le couleurs ou les distributions de couleurs dont nous venons de parler. Par exemple dans le nid peuplé de bourdons *dont le derrière seul étoit feuillemorte*, j'en ai vu naître quelques-uns qui avoient sur le corps *une ou deux bandes transversales de couleur de citron* (i).” Again, I have myself seen this insect entering the nidus of *A. lapidaria*, but what appears to do away all doubt upon the subject, I saw this insect in the collection of the celebrated Peter Collinson, with a memorandum affixed to it, that he had seen it connected with *A. lapidaria*.

Memoriae Johannis Ray *in παν*, *hæc Apis inscribitur.*

This *Apis* is so similar to *A. lapidaria*, that, if known, it has probably been confounded with it, it differs, however, in the shape of its exterior palpi (*k*) and abdomen. Its corbicula is red, and its anus is paler. The accurate eye of Ray detected these differences, and he has given it as a distinct species, for his description makes it evident that he means the same insect. “Superiore” (viz. *A. lapidaria*) “duplo minor est,” says he, “et insigni notâ ab eo differt, nimirum quod superius inter-

(*k*) This is a strong character, as the exterior palpi in all the aculeates, at least, of *A. lapidaria* are elongate, very slender, and filiform. I have affixed a mark of interrogation to this character, because the envelope, in which I preserve this proboscis, is labelled *A. lapidaria second magnitude*. But as I formerly looked upon *A. Raiella* as a variety of that insect, and all the others have similar posterior palpi, I have little or no doubt that this proboscis belongs to the one before us.

nomium

nodium crurum posteriorum (quod compressum et latum est) ad margines fimbriâ pilorum rubentium cingitur, cum in illo pili / setulæ internodium istud cingentes nigri sunt, reliquæ scilicet lanugini colores." This species differs, likewise, from *A. lapidaria* in its place and mode of nidification, as we learn from the same illustrious author. " Nidi-fieat et mellificat in gramine eodem quo sequens (viz. *A. muscorum*) modo."

108. A. atra, hirsuta, ano fulvo, alis nigricantibus. *rupestris.*

Obs. *Omnium ferè nostratum hæc Apis maxima.*

This gigantic *Apis* is often confounded with the female of *A. lapidaria*, and Fabricius, who has described it under the name of *A. rupestris*, seems to doubt whether it ought to be regarded as distinct: but its black wings, longer than the body, and of a substance intermediate between corium and membrane, would sufficiently establish its claim to the rank of a species, without the aid of other characters; it possesses others, however, which establish its identity beyond all doubt, for, with *A. campestris*, *Barbutella*, and *vestalis*, before described, it is without the instruments for preparing and carrying masses of pollen upon its posterior tibiæ. I am not clear that *A. subterranea* of Christiùs is synonymous with it, as his figure gives a yellow band at the base of the thorax, it comes, however, very

very near to it. Geoffroy describes it, I think, under the same name, but neither of these is the *A. subterranea* of the Linnean cabinet.

109. A. atra, hirsuta, ano fusco; capite masculo *subterranea* subgloboso; maxillis supra tomentoso-fulvis.

vis

vis piceis tenuioribus ferrugineis. *Pedes* atri, hirti. *Spinulae* castaneæ. *Scopulae* ferrugineæ, subauratae. *Digi* picei.

ABDOMEN subtriangulare, subacuminatum, hirsutum, atrum, ano minus nigro s. fusco, qui color e pilis sordide pallidis nigrisque mixtis exoritur.

Obs. *Ani pili pallidi densiores utrinque:*

This insect differs so very slightly from the specimen of the Linnean cabinet, which is an aculeate, that, I think, there can remain scarcely any doubt of its being the male of *A. subterranea*. Linneus referred to Ray n. 1. as synonymous with this, and adopted Geoffroy's reference, neither of which belong to the true *A. subterranea*. Ray evidently intending by his description *A. lapidaria*, and Geoffroy *A. rupestris*, the former expressly noticing the deep red anus that distinguishes the one, and the latter the black wings which form the characteristic of the other (*n*). Gmelin has rectified this error in some degree with respect to the synonym of Ray, by referring n. 1. to *A. lapidaria*, but then in its room he refers n. 2. to *A. subterranea*, which we have just seen belongs to another insect (*o*).

(*n*) Upon reconsidering the synonym of Geoffroy, I am not clear that it belongs to *A. rupestris*, as he says of his, " Il y a quelques poils jaunes mais peu apparens autour du col." But if it be not *A. rupestris*, it is clearly more nearly allied to it, than *A. subterranea*.

(*o*) After my *Synopsis Specierum* was printed, upon going over

DESCR. Acul.

CORPUS atrum, hirsutum.

CAPUT. Os et Nasus ferrugineo-barbata.

TRUNCUS immaculatus. Squanulæ nigro-piceæ. Alæ subcoloratæ, apice obscuriores, nervis nigricantibus. Pedes atri, hirti. Scopulæ atque Digitæ ferruginea.

ABDOMEN oblongum, totum atrum, hirsutum, ano minus nigro.

Obs. In nostro specimine abdomen anticè punctis duobus albidis insignitur. An sit hæc nota constans nondum compertum habeo.

Maris Caput triangulare. Maxillæ supra pallidæ, barbâ rufescenti. Antennæ truncò breviores, articulis subarcuatis. Abdomen ex ovo-to oblongum, ano obtuso. Venter nigricante hirsutulus.

I cannot help suspecting that the male of this may be the original *A. acervorum* of Linneus.over the male *Bomblinatrices*, I found the maxillæ of all were covered with pale or tawny down, though most remarkably in this species.

It wants, indeed, the "setulæ quædam circa collum sulphureæ," but in other respects it agrees well with his description, for it somewhat resembles *A. lucorum*, but it is narrower, and the terms "toto corpore nigro immaculato" exactly suit it. As another *Apis*, however, occupies its place in the Linnean cabinet, and the absence of the setulæ sulphureæ renders its claim to it somewhat dubious, I have given it under another name. Christius has a tolerable figure of the male as *A. retusa*. It is a coincidence rather singular, that *A. retusa* should be mistaken for *A. acervorum*, and, vice versa, *A. acervorum* for *A. retusa*.
